TECHNICAL COMMUNICATIONS

Price 1s. each except those otherwise marked

- No. 11. SPROUTED FODDER AND GERMINATED GRAIN IN STOCK FEEDING. I. Leitch,
M.A., D.Sc. 1939.
- No. 14. THE EFFICIENCY OF FARM ANIMALS IN THE CONVERSION OF FEEDINGSTUFFS
TO FOOD FOR MAN. (Mimeographic reproduction with addendum) I. Leitch
and W. Godden. 5s. 1953.
- No. 16. DIET IN RELATION TO REPRODUCTION AND THE VIABILITY OF THE YOUNG.
PART 1.: RATS AND OTHER LABORATORY ANIMALS. F. C. Russell, B.Sc. 6s.
1948.
- No. 17. STATISTICAL STUDIES OF RECORDED ENERGY EXPENDITURE OF MAN. PART 1:
BASAL METABOLISM RELATED TO SEX, STATURE, AGE, CLIMATE AND RACE.
M. H. Quenouille, A. W. Boyne, W. B. Fisher and I. Leitch. 6s. 1951.
- No. 18. HUMAN MILK. YIELD, PROXIMATE PRINCIPLES AND INORGANIC CONSTITUENTS.
S. D. Morrison. 10s. 6d. 1952.

Orders and remittances should be sent to: COMMONWEALTH AGRICULTURAL BUREAUX,
CENTRAL SALES BRANCH, Farnham Royal, Bucks., England.

Nutrition Abstracts and Reviews

REVIEW ARTICLES reprinted from Nutrition Abstracts and Reviews

Price 1s. each except where a special price is given
(Those marked with an asterisk are out of print.)

- DIET AND DENTAL DISEASE. S. J. Cowell, 1936, 6, 567.
- *A REVIEW OF RECENT WORK ON DIETARY REQUIREMENTS IN PREGNANCY AND LACTATION, WITH AN ATTEMPT TO ASSESS HUMAN REQUIREMENTS. R. C. Gairty and D. Stiven, 1938, 6, 555.
- AN ANALYSIS AND COMPARISON OF DIFFERENT METHODS OF CALCULATING THE ENERGY VALUE OF DIETS. N. B. Morey, 1936, 8, 1.
- THE PROTEIN REQUIREMENTS OF LACTATION. S. Morris, 1936, 6, 273.
- THE DETERMINATION OF THE CALCIUM REQUIREMENTS OF MAN. I. Leitch, 1937, 6, 553; 1938, 8, 1.
- THE RELATIVE POTENCY OF VITAMIN D FROM DIFFERENT SOURCES. E. M. Hume, 1937, 6, 891.
- NUTRITIONAL SCIENCE AND ITS SOCIAL ASPECTS. Sir Richard Gregory, Bart., 1937, 7, 1.
- THE DETERMINATION OF THE PROTEIN REQUIREMENTS OF MAN. I. Leitch and J. Duckworth, 1937, 7, 257.
- THE DETERMINATION OF THE CALORIE REQUIREMENTS OF MAN. J. B. Orr and I. Leitch, 1938, 7, 509.
- RECENT RESEARCH ON VITAMIN E. A. L. Bacharach, 1938, 7, 811.
- *TABLES OF THE VITAMIN CONTENT OF HUMAN AND ANIMAL FOODS. M. A. B. Fixsen and M. H. Roscoe, 1938, 7, 823.
- *THE VITAMIN CONTENT OF HUMAN FOODS AS AFFECTED BY PROCESSES OF COOKING AND CANNING (with tables). M. A. B. Fixsen, 1938, 8, 281.
- THE NUTRITIVE VALUE OF WHEATEN FLOUR AND BREAD. A. M. Copping, 1939, 8, 555.
- MAGNESIUM IN ANIMAL NUTRITION. J. Duckworth, 1939, 8, 841.
- PASTEURISATION OF MILK: SOME RECENT ASPECTS. H. D. Kay, 1939, 9, 1.
- CHRONIC FLUORINE INTOXICATION IN DOMESTIC ANIMALS. A. W. Peirce, 1939, 9, 253.
- *THE SIGNIFICANCE OF THE "TRACE ELEMENTS" IN NUTRITION. E. J. Underwood, 1940, 9, 515.
- TABLES OF THE VITAMIN CONTENT OF HUMAN AND ANIMAL FOODS. M. A. B. Fixsen and M. H. Roscoe, 1940, 9, 795. Price 2s. 6d.
- QUALITY AND QUANTITY OF PROTEIN IN RELATION TO HUMAN HEALTH AND DISEASE. D. P. Cuthbertson, 1940, 10, 1.
- VITAMIN A DEFICIENCY AND REQUIREMENTS OF FARM MAMMALS. G. H. Hart, 1940, 10, 261.
- THE DISTRIBUTION OF NICOTINIC ACID IN HUMAN AND ANIMAL FOODS. A. L. Bacharach, 1941, 10, 459.
- THE EFFECT OF DIET ON THE CHEMICAL COMPOSITION, NUTRITIVE VALUE AND HATCHABILITY OF THE EGG. E. M. Cruickshank, 1941, 10, 645.
- NUTRITION AND HUMAN WELFARE. J. B. Orr, 1941, 11, 3.
- INDIAN DIETS AND THEIR IMPROVEMENT. W. R. Aykroyd, 1941, 11, 171.
- COMPONENTS OF THE VITAMIN B₂ COMPLEX. S. Lepkovsky, 1942, 11, 363.
- THE EVOLUTION OF DIETARY STANDARDS. I. Leitch, 1942, 11, 509.
- CHOLESTEROL METABOLISM. R. P. Cook, 1942, 12, 1.
- THE MAGNESIUM REQUIREMENTS OF MAN IN RELATION TO CALCIUM REQUIREMENTS, WITH OBSERVATIONS ON THE ADEQUACY OF DIETS IN COMMON USE. J. Duckworth and G. M. Watnock, 1942, 12, 167.
- THE RÔLE OF VITAMIN CONCENTRATES IN WAR AND IN POST-WAR FOOD RELIEF IN EUROPE. V. P. Sydenstricker, 1943, 12, 339.
- SOME PECULIARITIES OF RUMINANT NUTRITION. H. Goss, 1943, 12, 531.
- THE PRESERVATION OF FOOD. Sir J. Barcroft, 1943, 13, 1.
- *SOME CAUSES OF VARIATION IN THE VITAMIN CONTENT OF PLANTS GROWN FOR FOOD. L. A. Maynard and K. C. Beeson, 1943, 13, 155.
- THE NUTRITIONAL REQUIREMENTS OF THE DOG. L. Michaud and C. A. Elvehjem, 1944, 13, 323.
- PROTEIN HYDROLYSATES IN INTRAVENOUS ALIMENTATION. W. E. Gaunt, 1944, 13, 501.
- NUCLEIC ACIDS AND TISSUE GROWTH. J. N. Davidson and C. Weymouth, 1944, 14, 1.
- THE WATER ECONOMY OF FARM ANIMALS. I. Leitch and J. S. Thomson, 1944, 14, 197.
- SOME ASPECTS OF RIBOFLAVIN NUTRITION IN MAN. A. M. Copping, 1945, 14, 433.
- *THE REQUIREMENT FOR CALCIUM DURING GROWTH. J. O. Holmes, 1945, 14, 597.
- *THE STORAGE OF PROTEIN IN THE ADULT ANIMAL. H. W. Kosterlitz and R. M. Campbell, 1945, 15, 1.
- *DIETARY DEFICIENCIES AND ENERGY METABOLISM. M. Kleiber, 1945, 15, 207.
- THE AMOUNTS OF VITAMIN B₁ IN CEREALS AND THE EXTENT TO WHICH THEY SUPPLY HUMAN REQUIREMENTS IN VARIOUS DIETARIES. W. I. M. Holman, 1946, 15, 387. Price 2s. 6d.
- DIETARY REQUIREMENTS IN HUMAN PREGNANCY AND LACTATION. A REVIEW OF RECENT WORK. R. C. Gairty and H. O. Wood, 1946, 15, 591. Price 3s. 6d.
- THE VITAMIN REQUIREMENTS OF SWINE. N. R. Ellis, 1946, 16, 1.
- *THE CORRELATION OF THE AMINO-ACID COMPOSITION OF PROTEINS WITH THEIR NUTRITIVE VALUE. R. J. Block and H. H. Mitchell, 1946, 16, 249. Price 3s. 6d.
- MICROBIOLOGICAL METHODS FOR THE ESTIMATION OF AMINO-ACIDS. B. S. Schweigert and E. S. Snell, 1947, 16, 497. Price 2s. 6d.
- *PRODUCTION AND MODIFICATION OF LIVER DISEASE BY DIET. L. E. Glynn, 1947, 16, 751.
- *THE RÔLE OF THE MICROFLORA OF THE ALIMENTARY TRACT OF HERBIVORA WITH SPECIAL REFERENCE TO RUMINANTS. F. Baker, S. T. Harriss, A. T. Phillips, M. L. McNaught, J. A. B. Smith, S. K. Kon and J. W. G. Porter, 1947, 17, 1. Price 4s.

REVIEW ARTICLES reprinted from Nutrition Abstracts and Reviews (continued)

- THE VALUE OF CAPILLARY STRENGTH TESTS IN THE DIAGNOSIS OF VITAMIN C AND VITAMIN P DEFICIENCY IN MAN. H. N. Munro, S. Lazarus and G. H. Bell, 1947, 17, 291. Price 2s.
- THE INFLUENCE OF DIET ON PANDORONTAL DISEASE. J. D. King, 1948, 17, 569. Price 2s. 6d.
- METHODS OF ESTIMATING PLASMA AND TOTAL RED CELL VOLUME. E. B. Reeve, 1948, 17, 811. Price 2s.
- *THE NUTRITIVE VALUE OF SILAGE AND DRIED GRASS. S. J. Watson, 1948, 18, 1. Price 1s. 6d.
- *THE EFFECT OF MILLING UPON THE NUTRITIVE VALUE OF WHEATEN FLOUR AND BREAD. M. C. Dawbarn, 1949, 18, 691. Price 2s.
- THE CALORIC REQUIREMENT OF ADULT MAN. Ancel Keys, 1949, 19, 1.
- THE MINERAL REQUIREMENTS AND METABOLISM OF POULTRY. Cyril Tyler, 1948, 18, 261, 473; 1949, 19, 263. Price 6s.
- TECHNIQUE AND INTERPRETATION OF DIETARY SURVEYS. I. Leitch and F. C. Aitken, 1950, 19, 507.
- THE VITAMIN REQUIREMENTS OF POULTRY. A. S. Hogan, 1950, 19, 751. Price 6s.
- ENERGY FEEDING STANDARDS FOR DAIRY CATTLE. K. L. Blaxter, 1950, 20, 1. Price 3s.
- EVALUATION OF LEANNESS-FATNESS IN MAN: A SURVEY OF METHODS. J. Brožek and Ancel Keys, 1950, 20, 247. Price 2s.
- THE CAUSATION OF PELLAGRA. Harriette Chick, 1951, 20, 523. Price 2s.
- *VITAMIN B₁₂. PART I. E. Lester Smith, 1951, 20, 795. Price 2s.
- VITAMIN B₁₂. PART II. A REVIEW OF THE CLINICAL ASPECTS. C. C. Ungley, 1951, 21, 1. Price 4s.
- EXPANSION OF LIVESTOCK PRODUCTION IN RELATION TO HUMAN NEEDS. Ralph W. Phillips, 1951, 21, 241. Price 2s.
- THE METABOLISM OF FAT IN THE MAMMARY GLAND AND FOETAL TISSUES, WITH REFERENCE TO THE APPLICATION OF ISOTOPIC TRACERS. G. Popják, 1952, 21, 535. Price 2s. 6d.
- THE FLUORINE PROBLEM IN LIVESTOCK FEEDING. H. H. Mitchell and Marjorie Edman, 1952, 21, 787. Price 2s.
- VITAMIN E IN THE NUTRITION OF FARM ANIMALS. K. L. Blaxter and F. Brown, 1952, 22, 1. Price 2s. 6d.
- MEAL HABITS AND THEIR EFFECTS ON PERFORMANCE. R. C. Hutchinson, 1952, 22, 283. Price 2s.
- THE STORAGE OF ELEMENTS IN THE SKELETON. J. Duckworth and R. Hill, 1953, 23, 1. Price 2s.
- FAO. W. R. Aykroyd, 1953, 23, 229. Price 2s.
- ANTIBIOTICS IN NUTRITION. R. Braude, S. K. Kon and J. W. G. Porter, 1953, 23, 473. Price 3s.
- NUTRITION AND HOST-HELMINTH RELATIONSHIPS. G. C. Hunter, 1953, 23, 705. Price 2s.
- THE DIAGNOSIS OF MALNUTRITION IN MAN. A. M. Thomson and D. L. Duncan, 1954, 24, 1. Price 3s.
- SECULAR CHANGE IN THE HEIGHT OF BRITISH ADULTS. A. W. Boyne and I. Leitch, 1954, 24, 255. Price 2s.
- THE SEA AND WORLD FOOD SUPPLIES. D. B. Finn, 1954, 24, 487. Price 2s.
- LAND USE AND DEVELOPMENT IN AUSTRALIA. C. G. Stephens, 1954, 24, 731. Price 2s.
- THE NUTRITION OF THE HORSE. N. Olsson and A. Ruudvold, 1955, 25, 1. Price 3s. 6d.
- When ordering please quote authors' names and dates: e.g., Mowry (1938); Fixsen and Roscoe (1940). Orders and remittances should be sent to: THE SECRETARY, "NUTRITION" ABSTRACTS AND REVIEWS, Rowett Institute, Bucksburn, Aberdeenshire, Scotland.*

RESEARCH JOURNALS

PUBLISHED BY

NATIONAL RESEARCH COUNCIL OF CANADA

Under the authority of the Chairman of the Committee of the Privy Council on Scientific and Industrial Research, the National Research Council issues seven journals devoted to the publication of the results of original scientific research. Most of the research on which the papers are based is carried out in Canada, but contributions from workers in other countries are accepted also. Papers are published in English or French.

The seven journals, their frequency of publication, and the annual subscription rates are :-

Canadian Journal of Biochemistry and Physiology (formerly <i>Canadian Journal of Medical Sciences</i>)	Bi-monthly	\$3.00
Canadian Journal of Botany	Bi-monthly	\$4.00
Canadian Journal of Chemistry	Monthly	\$5.00
Canadian Journal of Microbiology	Bi-monthly	\$3.00
Canadian Journal of Physics	Monthly	\$4.00
Canadian Journal of Technology	Bi-monthly	\$3.00
Canadian Journal of Zoology	Bi-monthly	\$3.00

Volume 1 of the "Canadian Journal of Microbiology" will consist of 9 numbers, i.e., August, 1954, to December, 1955.

Manuscripts for consideration should be submitted to the Editor-in-Chief, National Research Council, Ottawa, Canada.

Requests for subscriptions should be mailed to the National Research Council, Ottawa 2, Canada, and remittances made payable to the Receiver General of Canada, credit National Research Council.

The British Journal of NUTRITION

Vol. 9, No. 1, 1955. 30s. net

- D. E. TRIBE and J. G. GORDON. Choice of diet by rats. 3. The importance of the sense of smell in the choice of diets deficient in the vitamin B complex.
- A. N. WOLDEN and C. E. WATKINSON. The effect of environmental temperature on the urinary excretion of riboflavin by the dog.
- J. H. B. ROY, J. G. SHILLAM, K. W. G. SHILLAM, P. L. INGRAM and P. C. WOOD. The nutritive value of colostrum for the calf. 10. The relationship between the period of time that a calfhouse has been occupied and the incidence of scouring and mortality in young calves.
- R. PASMORE, A. P. MEIKLEJOHN, A. D. DEWAR, and ROSEMARY K. THOW. Energy Utilization in overfed thin young men.
- R. PASMORE, A. P. MEIKLEJOHN, A. D. DEWAR and ROSEMARY K. THOW. An analysis of the gain in weight of overfed thin young men.
- A. E. P. WALKER, DOROTHY C. FLECHER, EMMERENTIA S. P. STYDUM and MARIANNE ANDERSSON. Food preparation used in weaning urban Bangian infants.
- E. AARS-JENSEN, P. F. ENGBL, J. P. FUCHS and H. DAM. The role of fat in the diet of rats. 7. The influence on growth of diets supplemented with raw skim milk, linoleic acid or both; and of raw casein compared with alcohol-extracted casein.
- JUDITH M. HATCHER, ELIZABETH M. CHESMAN, ALICE M. COPPING and ANNE D. TRUSLER. The effect of vitamin B₆ on the growth and the blood picture of the rat.
- S. HALBY, E. J. DIAMANT and K. GUGGENHEIM. The effect of antibiotics on the metabolism of nicotinic acid, biotin and folic acid in rats.
- J. H. MOORE and C. TYLER. Studies on the intestinal absorption and excretion of calcium and phosphorus in the pig. 1. A critical study of the Berglund technique for investigating the intestinal absorption and excretion of calcium and phosphorus.
- J. H. MOORE and C. TYLER. Studies on the intestinal absorption and excretion of calcium and phosphorus in the pig. 2. The intestinal absorption and excretion of radioactive calcium and phosphorus.
- J. H. B. ROY, K. W. G. SHILLAM, J. G. SHILLAM and P. L. INGRAM. The nutritive value of colostrum for the calf. 11. The effect of aureomycin on the performance of colostrum-deprived calves.
- D. E. TRIBE. Choice of diet by rats. 4. The choice of purified food constituents during growth, pregnancy and lactation.
- M. E. COATES, M. K. DAVIES and S. K. KON. The effect of antibiotics on the intestine of the duck.

Published for The Nutrition Society by the Cambridge University Press, Bentley House, 200 Euston Road, N.W.1. The combined subscription for *The British Journal of Nutrition* (4 parts a year) and *The Proceedings of the Nutrition Society* (2 parts a year) is £6. Single issues of either publication are 30s. each, plus postage.

Zentralblatt für Veterinärmedizin

Prof. Dr. M. LERCHE
Free University, Berlin

Edited by
and

Prof. Dr. H. SPÖRRI
University, Zürich

with the collaboration of many scientists of international repute

The *Zentralblatt für Veterinärmedizin* is an international journal which publishes the results of research in all branches of veterinary medicine. The journal provides the several disciplines of veterinary medicine with information on current aims and results in all the fields of research; it offers the information also to allied sciences so that a fruitful interchange of knowledge and ideas may develop.

Original papers appear in German, English, French or Spanish with summaries in all four languages.

In scope and volume the *Zentralblatt* exceeds other journals of veterinary medicine and in the presentation and value of the papers published is comparable with the best journals serving other sciences.

There are annually 6 parts each of 6 or 7 sheets. The parts of one calendar year form a volume. Price per sheet (16 pages) about DM. 3. Each part is priced separately.

Zeitschrift für Tierzüchtung und Züchtungsbiologie

Founded in 1924 by C. KRONACHER

Edited by Prof. Dr. J. SCHMIDT
with the collaboration of many international authorities

This journal is the recognised international organ for research on all branches of animal breeding, the biology of animal production and related subjects: racial biology, evolution, genetics, development, growth, constitution and adaptation; osteology and the mechanics of the skeleton, animal nutrition and animal hygiene.

It provides for all technical experts, veterinary officers and biologists a valuable survey of current research.

There are annually about 6 parts and 4 parts are a volume. A part is of about 6 sheets. Price per sheet of 16 pages about DM. 4. Each part is separately priced.

Published by PAUL PAREY, Lindenstr. 44/47, Berlin, S.W.68 (Westberlin)

FOOD SCIENCE ABSTRACTS

A bi-monthly journal of abstracts and reviews giving scientific and technical information about the processing, storage and transport, and the behaviour, properties, composition and quality of foods

It is divided into sections on: meat; poultry and game; fish and shellfish; eggs; dairy produce; fats and oils; fruits and vegetables; cereal grains, pulses, nuts, animal feeding-stuffs, etc.; sugar, syrup, confectionery, tea, coffee, cocoa, spices, flavours, condiments; general processing and chemical engineering; physics and refrigerating engineering; packaging methods and materials; and miscellaneous.

EACH ANNUAL VOLUME CONTAINS OVER 3,000 ABSTRACTS,
AND A SUBJECT AND AUTHOR INDEX

Review articles published in 1954 included the following:—

“The Preservation of Foods with Ionizing Radiations.”

“Chemicals and Food.”

“Dehydrofreezing of Fruits and Vegetables.”

“The Bacterial Contamination of Foods.”

FOOD SCIENCE ABSTRACTS is prepared by the Food Investigation Organization of the Department of Scientific and Industrial Research, and is published by H.M. Stationery Office. It may be purchased direct from H.M. Stationery Office at the following addresses or through any bookseller:—

York House, Kingsway, London, W.C.2; 423 Oxford Street, London, W.1;
(Post Orders—P.O. Box No. 569, London, S.E.1); 13a Castle Street, Edinburgh, 2;
39 King Street, Manchester, 2; 2 Edmund Street, Birmingham, 3; 1 St. Andrew's
Crescent, Cardiff; Tower Lane, Bristol, 1; 80 Chichester Street, Belfast.

Subscription Rates for 1955

Annual subscription (including index) . . .	£4 including postage
Per number	12s. 6d. (by post 12s. 10d.)
Annual index	12s. 6d. (by post 12s. 10d.)
20 per cent. reduction for bulk orders of 100 copies or more	

Correspondence should be addressed to:—

3. VITAMINS			
General	64	Metabolism of Cells, Tissues, etc.	
Vitamin A	65	GENERAL PHYSIOLOGY	178
" D	73	GROWTH AND METABOLISM OF TUMOUR CELLS	183
" E	77	Metabolism of Growth, Reproduction and Senescence	
" K	79	GROWTH	185
" B Complex: General	80	REPRODUCTION AND LACTATION: MAMMALS	189
" B ₁ (Aneurin, Thiamine)	83	" : BIRDS	191
		SENESCENCE	192

	PAGE		PAGE
Experimental Studies of Immunity and Micro-organisms	193	GASTRO-INTESTINAL CONDITIONS	247
Miscellaneous Feeding Experiments	197	THYROID DISEASE	249
General Metabolism and Feeding Habits of Animals other than Mammals and Birds	205	ANAEMIA	249
		OTHER CONDITIONS	250
 5. HUMAN DIET IN RELATION TO HEALTH AND DISEASE			
Diet		6. FEEDING OF ANIMALS	
REQUIREMENTS	207	General, including Digestibility Trials	252
FEEDING OF INFANTS AND CHILDREN	207	Horses	257
DIETARY SURVEYS AND INDIVIDUAL STUDIES	210	Cattle	
GENERAL STUDIES: DIET PLANNING: EDUCATION	214	GROWTH AND FATTENING	258
Food Economics and Statistics	217	MILK PRODUCTION	262
Diet in Etiology of Disease		REPRODUCTION	267
METHODS OF ASSESSING STATE OF HEALTH	219	Sheep	267
GENERAL STUDIES	219	Pigs	270
DEFICIENCY DISEASES		Goats, Rabbits and other Mammals	276
General	222	Poultry	
Vitamin A	224	GROWTH AND FATTENING	278
" D	227	EGG PRODUCTION	284
" E	229	Other Birds	286
" B Complex	231	Food Economics and Statistics	286
" C	240	Diet in Etiology of Disease	
Other Vitamins	242	GENERAL	289
Other Elements	nil	DEFICIENCY DISEASES	292
DENTAL DISEASES	243	DISEASES OF METABOLISM	295
POISONS: PATHOGENIC ORGANISMS: FOOD LAWS	245	POISONS OCCURRING IN FOOD	296
IMMUNITY	nil	MICRO-ORGANISMS OCCURRING IN FOOD	nil
Therapeutic and Preventive Diets		IMMUNITY	299
GENERAL	246	7. BOOK REVIEWS	300
DIABETES	246	8. FOOD AND AGRICULTURE ORGANIZATION OF THE UNITED NATIONS	306
		9. DEPARTMENTAL AND OTHER REPORTS	307

AUTHOR INDEX

* Nomenclature of Amino-Acids

In Review Articles it will be that agreed upon by the Editors of the *Journal of the Chemical Society* and of the *Biochemical Journal* published in *Biochem. J.*, 1948, 42, 1.

In Abstracts the nomenclature will be that used in the paper being abstracted.

LIST OF JOURNALS SCRUTINISED

(Arranged alphabetically according to Contracted Title)

<i>Title of Journal</i>	<i>Contracted Title</i>	<i>Last Number Scrutinised</i>	<i>Place of Publication</i>
Acta Academiae Scientiarum Naturalium Moravo-Silesiace	Acta Acad. Sci. Nat. Moravo-Siles.	1952, 24	Brno, Czechoslovakia
Acta Agraria Fennica	Acta agral. fenn.	1953, 82, No. 1/2	Helsinki, Finland
Acta Agriculturae Scandinavica	Acta Agric. scand.	1954, 4, No. 3	Stockholm, Sweden
Acta Agronomica	Acta agronom., Colombia	1954, 4, No. 3	Palmira, Colombia
Acta Biologica Hungarica	Acta biol. hung.	1953, 4, No. 3/4	Budapest, Hungary
Acta Chemica Scandinavica	Acta chem. scand.	1954, 8, No. 5	Copenhagen, Denmark
Acta Chimica Hungarica	Acta chim. hung.	1954, 4, No. 1	Budapest, Hungary
Acta Cientifica Venezolana	Acta cientif. venezol.	1953, 4, No. 5	Caracas, Venezuela
Acta Gastro-Enterologica Belgica	Acta gastro-enterol. belg.	1954, 17, No. 8/9	Brussels, Belgium
Acta Gerontologica	Acta gerontol.	1954, 4, No. 1	Milan, Italy
Acta Leidensia	Acta leidensia	1953, 23	Leyden, Holland
Acta Medica et Biologica	Acta med. biol.	1954, 2, No. 1	Kilgata, Japan
Acta Medica Hungarica	Acta med. hung.	1954, 5, No. 3/4	Budapest, Hungary
Acta Medica Jugoslavica	Acta med. jugoslav.	1954, 8, No. 1	Belgrade, Yugoslavia
Acta Medica Philippina	Acta med. philipp.	1952-53, 8, No. 4	Manila, Philippines
Acta Medica Scandinavica	Acta med. scand.	1954, 149, No. 5	Stockholm, Sweden
Acta Paediatrica	Acta paediat.	1954, 43, No. 4	Stockholm, Sweden
Acta Paediatrica Belgica	Acta paediat. belg.	1954, 8, No. 2	Brussels, Belgium
Acta Pathologica et Microbiologica Scandinavica	Acta pathol. microbiol. scand.	1954, 35, No. 1	Copenhagen, Denmark
Acta Physiologica Hungarica	Acta physiol. hung.	1954, 6, No. 1	Budapest, Hungary
Acta Physiologica et Pharmacologica Neerlandica	Acta physiol. pharmacol. neerl.	1954, 3, No. 1	Amsterdam, Holland
Acta Physiologica Scandinavica	Acta physiol. scand.	1954, 31, No. 2/3	Stockholm, Sweden
Acta Radiologica	Acta radiol.	1954, 42, No. 2	Stockholm, Sweden
Acta Scholae Medicinalis in Kioto	Acta Scholae med. Univ. Kioto	1954, 31, No. 3	Kioto, Japan
Acta Societatis Medicorum Upsalienis	Acta Soc. Med. upsalien.	1954, 59, No. 3/4	Uppsala, Sweden
Acta Veterinaria	Acta vet., Belgrade	1954, 4, No. 2	Belgrade, Yugoslavia
Acta Vitaminologica	Acta vitaminol.	1954, 8, No. 2	Milan, Italy
Advances in Biological and Medical Physics	Advances in Biol. Med. Phys.	1953, 3	New York, U.S.A.

22 JUL 1958

Books on Animal Nutrition and Allied Sciences

of all publishers supplied
from stock.

FOREIGN BOOKS NOT IN STOCK OBTAINED
TO ORDER.

Scientific Lending Library

ANNUAL SUBSCRIPTION, TOWN OR COUNTRY,
FROM TWENTY-FIVE SHILLINGS

Bi-monthly list of New Books and New Editions
added to the Library, sent post free to any
address on request.

The Library Catalogue revised to December,
1949. To subscribers, 17s. 6d. net. To non-
subscribers, 35s. net; postage 1s. 6d. Supple-
ment 1950 to 1952. To subscribers 38s. net.
To non-subscribers 6s. net; postage 6d.

Second-Hand Books

A constantly changing large stock of second-
hand recent editions available. Large and small
collections bought.

H. K. LEWIS & Co. Ltd.

LONDON: 136 Gower Street, W.C.1

Telephone: EUSon 4282 (7 lines)

Commonwealth Bureau of Animal Nutrition

Rowett Research Institute, Bucksburn, Aberdeenshire, Scotland

TECHNICAL COMMUNICATIONS

Price 1s. each except those otherwise marked

- No. 11. SPROUTED FODDER AND GERMINATED GRAIN IN STOCK FEEDING. I. Leitch, M.A., D.Sc. 1939.
- No. 14. THE EFFICIENCY OF FARM ANIMALS IN THE CONVERSION OF FEEDINGSTUFFS TO FOOD FOR MAN. (Mimeographic reproduction with addendum) I. Leitch and W. Godden. 5s. 1953.
- No. 16. DIET IN RELATION TO REPRODUCTION AND THE VIABILITY OF THE YOUNG. PART 1.: RATS AND OTHER LABORATORY ANIMALS. F. C. Russell, B.Sc. 6s. 1948.
- No. 17. STATISTICAL STUDIES OF RECORDED ENERGY EXPENDITURE OF MAN. PART 1.: BASAL METABOLISM RELATED TO SEX, STATURE, AGE, CLIMATE AND RACE. M. H. Quenouille, A. W. Boyne, W. B. Fisher and I. Leitch. 6s. 1951.
- No. 18. HUMAN MILK. YIELD, PROXIMATE PRINCIPLES AND INORGANIC CONSTITUENTS. S. D. Morrison. 10s. 6d. 1952.

Orders and remittances should be sent to: COMMONWEALTH AGRICULTURAL BUREAUX,
CENTRAL SALES BRANCH, Farnham Royal, Bucks., England.

Nutrition Abstracts and Reviews

REVIEW ARTICLES reprinted from Nutrition Abstracts and Reviews

Price 1s. each except where a special price is given
(Those marked with an asterisk are out of print.)

- DIET AND DENTAL DISEASE. S. J. Cowell, 1936, 5, 567.
- *A REVIEW OF RECENT WORK ON DIETARY REQUIREMENTS IN PREGNANCY AND LACTATION, WITH AN ATTEMPT TO ASSESS HUMAN REQUIREMENTS. R. C. Garry and D. Stiven, 1938, 5, 855.
- AN ANALYSIS AND COMPARISON OF DIFFERENT METHODS OF CALCULATING THE ENERGY VALUE OF DIETS. N. B. Morey, 1936, 6, 1.
- THE PROTEIN REQUIREMENTS OF LACTATION. S. Morris, 1936, 6, 273.
- THE DETERMINATION OF THE CALCIUM REQUIREMENTS OF MAN. I. Leitch, 1937, 6, 553; 1938, 8, 1.
- THE RELATIVE POTENCY OF VITAMIN D FROM DIFFERENT SOURCES. E. M. Hume, 1937, 6, 891.
- NUTRITIONAL SCIENCE AND ITS SOCIAL ASPECTS. Sir Richard Gregory, Bart., 1937, 7, 1.
- THE DETERMINATION OF THE PROTEIN REQUIREMENTS OF MAN. I. Leitch and J. Duckworth, 1937, 7, 257.
- THE DETERMINATION OF THE CALORIE REQUIREMENTS OF MAN. J. B. Orr and I. Leitch, 1938, 7, 509.
- RECENT RESEARCH ON VITAMIN E. A. L. Bacharach, 1938, 7, 811.
- *TABLES OF THE VITAMIN CONTENT OF HUMAN AND ANIMAL FOODS. M. A. B. Fixsen and M. H. Roscoe, 1938, 7, 823.
- *THE VITAMIN CONTENT OF HUMAN FOODS AS AFFECTED BY PROCESSES OF COOKING AND CANNING (with tables). M. A. B. Fixsen, 1938, 8, 281.
- THE NUTRITIVE VALUE OF WHEATEN FLOUR AND BREAD. A. M. Copping, 1939, 8, 555.
- MAGNESIUM IN ANIMAL NUTRITION. J. Duckworth, 1939, 8, 841.
- PASTEURISATION OF MILK: SOME RECENT ASPECTS. H. D. Kay, 1939, 9, 1.
- CHRONIC FLUORINE INTOXICATION IN DOMESTIC ANIMALS. A. W. Peirce, 1939, 9, 253.
- *THE SIGNIFICANCE OF THE "TRACE ELEMENTS" IN NUTRITION. E. J. Underwood, 1940, 9, 515.
- TABLES OF THE VITAMIN CONTENT OF HUMAN AND ANIMAL FOODS. M. A. B. Fixsen and M. H. Roscoe, 1940, 9, 795. Price 2s. 6d.
- QUALITY AND QUANTITY OF PROTEIN IN RELATION TO HUMAN HEALTH AND DISEASE. D. P. Cuthbertson, 1940, 10, 1.
- VITAMIN A DEFICIENCY AND REQUIREMENTS OF FARM MAMMALS. G. H. Hart, 1940, 10, 261.
- THE DISTRIBUTION OF NICOTINIC ACID IN HUMAN AND ANIMAL FOODS. A. L. Bacharach, 1941, 10, 459.
- THE EFFECT OF DIET ON THE CHEMICAL COMPOSITION, NUTRITIVE VALUE AND HATCHABILITY OF THE EGG. H. M. Cruickshank, 1941, 10, 645.
- NUTRITION AND HUMAN WELFARE. J. B. Orr, 1941, 11, 3.
- INDIAN DIETS AND THEIR IMPROVEMENT. W. R. Aylcroyd, 1941, 11, 171.
- COMPONENTS OF THE VITAMIN B₁ COMPLEX. S. Lepkovsky, 1942, 11, 363.
- THE EVOLUTION OF DIETARY STANDARDS. I. Leitch, 1942, 11, 509.
- CHOLESTEROL METABOLISM. R. P. Cook, 1942, 12, 1.
- THE MAGNESIUM REQUIREMENTS OF MAN IN RELATION TO CALCIUM REQUIREMENTS, WITH OBSERVATIONS ON THE ADEQUACY OF DIETS IN COMMON USE. J. Duckworth and G. M. Warnock, 1942, 12, 167.
- THE RÔLE OF VITAMIN CONCENTRATES IN WAR AND IN POST-WAR FOOD RELIEF IN EUROPE. V. P. Sydenstricker, 1943, 12, 839.
- SOME PECULIARITIES OF RUMINANT NUTRITION. H. Goss, 1943, 12, 531.
- THE PRESERVATION OF FOOD. Sir J. Barcroft, 1943, 13, 1.
- *SOME CAUSES OF VARIATION IN THE VITAMIN CONTENT OF PLANTS GROWN FOR FOOD. L. A. Maynard and K. C. Beeson, 1943, 13, 155.
- THE NUTRITIONAL REQUIREMENTS OF THE DOG. L. Michaud and C. A. Elvehjem, 1944, 13, 323.
- PROTEIN HYDROLYSATES IN INTRAVENOUS ALIMENTATION. W. E. Gaunt, 1944, 13, 501.
- NUCLEIC ACIDS AND TISSUE GROWTH. J. N. Davidson and C. Waymouth, 1944, 14, 1.

RESEARCH JOURNALS

PUBLISHED BY

NATIONAL RESEARCH COUNCIL OF CANADA

Under the authority of the Chairman of the Committee of the Privy Council on Scientific and Industrial Research, the National Research Council issues seven journals devoted to the publication of the results of original scientific research. Most of the research on which the papers are based is carried out in Canada, but contributions from workers in other countries are accepted also. Papers are published in English or French.

The seven journals, their frequency of publication, and the annual subscription rates are:—

Canadian Journal of Biochemistry and Physiology (formerly <i>Canadian Journal of Medical Sciences</i>)	Bi-monthly	\$3.00
Canadian Journal of Botany	Bi-monthly	\$4.00
Canadian Journal of Chemistry	Monthly	\$5.00
Canadian Journal of Microbiology	Bi-monthly	\$3.00
Canadian Journal of Physics	Monthly	\$4.00
Canadian Journal of Technology	Bi-monthly	\$3.00
Canadian Journal of Zoology	Bi-monthly	\$3.00

Volume 1 of the "Canadian Journal of Microbiology" will consist of 9 numbers, *i.e.*, August, 1954, to December, 1955.

Manuscripts for consideration should be submitted to the Editor-in-Chief, National Research Council, Ottawa, Canada.

Requests for subscriptions should be mailed to the National Research Council, Ottawa 2, Canada, and remittances made payable to the Receiver General of Canada, credit National Research Council.

The British Journal of NUTRITION

Vol. 9, No. 2, 1955. 30s. net

- K. L. BLAXTER and J. A. F. ROOK. Energy and carbohydrate metabolism in magnesium-deficient calves.
- D. A. W. EDWARDS, W. H. HAMMOND, M. J. R. HEALY, J. M. TANNER and R. H. WHITEHOUSE. Design and accuracy of calipers for measuring subcutaneous tissue thickness.
- D. H. TOMLIN, K. M. HENRY and S. K. KON. The interstitial metabolism of calcium in the bones and teeth of rats.
- N. G. BAPTIST and B. V. DE MEL. Growth and amino-acid intakes of children on a cereal-legume-vegetable diet.
- W. BOLTON. The effect of injections of oestradiol dipropionate into immature pullets upon the manganese content of the blood plasma and of some tissues.
- T. MOORE and R. L. MITCHELL. Dental depigmentation and lowered content of iron in the incisor teeth of rats deficient in vitamin A or E.
- P. ROINE, T. ETTALA, A. RAHTO and U. VARTIOVAARA. The mode of action of aureomycin in the guinea-pig.
- R. BEAUCHE, R. C. CAMPBELL, I. A. M. LUCAS, J. R. LUSCOMBE, K. L. ROBINSON and J. H. TAYLOR. Antibiotics and endocrine stimulants as promoters of growth in fattening pigs.
- M. ANDERSSON and A. R. P. WALKER. Methionine concentration in South African Bantu breast milk.
- D. E. TRIBE and J. G. GORDON. Choice of diet by rats. 5. Choice of diets containing various members of the vitamin B complex.

Published for The Nutrition Society by the Cambridge University Press, Bentley House, 200 Euston Road, N.W.1. The combined subscription for *The British Journal of Nutrition* (4 parts a year) and *The Proceedings of the Nutrition Society* (2 parts a year) is £8. Single issues of either publication are 30s. each, plus postage.

Zentralblatt für Veterinärmedizin

Prof. Dr. M. LERCHE
Free University, Berlin

Edited by
and

Prof. Dr. H. SPÖRRI
University, Zürich

with the collaboration of many scientists of international repute

The *Zentralblatt für Veterinärmedizin* is an international journal which publishes the results of research in all branches of veterinary medicine. The journal provides the several disciplines of veterinary medicine with information on current aims and results in all the fields of research; it offers the information also to allied sciences so that a fruitful interchange of knowledge and ideas may develop.

Original papers appear in German, English, French or Spanish with summaries in all four languages.

In scope and volume the *Zentralblatt* exceeds other journals of veterinary medicine and in the presentation and value of the papers published is comparable with the best journals serving other sciences.

There are annually 6 parts each of 6 or 7 sheets. The parts of one calendar year form a volume. Price per sheet (16 pages) about DM. 3. Each part is priced separately.

Zeitschrift für Tierzüchtung und Züchtungsbiologie

Founded in 1924 by C. KRONACHER

Edited by Prof. Dr. J. SCHMIDT
with the collaboration of many international authorities

This journal is the recognised international organ for research on all branches of animal breeding, the biology of animal production and related subjects: racial biology, evolution, genetics, development, growth, constitution and adaptation; osteology and the mechanics of the skeleton, animal nutrition and animal hygiene.

It provides for all technical experts, veterinary officers and biologists a valuable survey of current research.

There are annually about 6 parts and 4 parts are a volume. A part is of about 6 sheets. Price per sheet of 16 pages about DM. 4. Each part is separately priced.

AUTHOR INDEX

* Nomenclature of Amino-Acids

In *Review Articles* it will be that agreed upon by the Editors of the *Journal of the Chemical Society* and of the *Biochemical Journal* published in *Biochem. J.*, 1948, 42, 1.

In *Abstracts* the nomenclature will be that used in the paper being abstracted.

Sir CHARLES JAMES MARTIN

C.M.G., M.B., F.R.C.P., D.Sc., M.A., LL.D., F.R.S.

(1866-1955)

THE Editors wish to place on record their appreciation of the valuable services rendered to this Journal by Sir Charles Martin who died on February 15, 1955. Sir Charles's service began with the establishment of the Journal in 1931, when Sir Walter Fletcher, Sir Frederick Hopkins, and he, were appointed the three representatives of the British Medical Research Council to the Committee of Management. In 1937 he replaced Professor J. J. R. Macleod as a co-editor with Sir John Boyd Orr and Dame Harriette Chick. In 1946 he and Sir John retired from the Editorial Board but both retained their connection with the Journal as Consulting Editors.

For more than half a century Sir Charles was an outstanding world figure in Medical research. His work in Australia, 1891 to 1903, and later, 1931 to 1933, helped to lay the foundation of Australian Medical Research and Education. The great contribution he made to the development of research in that continent was recognised at the centenary of Sydney University when the Prime Minister announced the foundation of two Charles James Martin Fellowships in Medicine for post-graduate research overseas. As Director of the Lister Institute in addition to his own important research he gave inspiration and guidance to the distinguished workers in that Institute who made such a notable contribution to our knowledge of the vitamins. Since his retirement in 1933, in addition to his work for this Journal, he continued to direct and take an active part in research in nutrition until a few weeks before he died. His house in Cambridge, part of which he fitted up as a laboratory, was a sort of Mecca for his large circle of admiring friends who came to discuss their research problems.

Sir Charles received many academic and other honours for the great contribution he made to the development of medical science. All who had the great privilege of working with him owe him a debt of gratitude for his unfailing wise counsel and friendship. We salute the passing of a great scientist and a great and good man.

TECHNICAL COMMUNICATIONS

Price 1s. each except those otherwise marked

- No. 11. SPROUTED FODDER AND GERMINATED GRAIN IN STOCK FEEDING. I. Leitch,
M.A., D.Sc. 1939.
- No. 14. THE EFFICIENCY OF FARM ANIMALS IN THE CONVERSION OF FEEDINGSTUFFS
TO FOOD FOR MAN. (Mimeographic reproduction with addendum) I. Leitch
and W. Godden. 5s. 1953.
- No. 16. DIET IN RELATION TO REPRODUCTION AND THE VIABILITY OF THE YOUNG.
PART I.: RATS AND OTHER LABORATORY ANIMALS. F. C. Russell, B.Sc. 6s.
1948.
- No. 17. STATISTICAL STUDIES OF RECORDED ENERGY EXPENDITURE OF MAN. PART I:
BASAL METABOLISM RELATED TO SEX, STATURE, AGE, CLIMATE AND RACE.
M. H. Quenouille, A. W. Boyne, W. B. Fisher and I. Leitch. 6s. 1951.
- No. 18. HUMAN MILK. YIELD, PROXIMATE PRINCIPLES AND INORGANIC CONSTITUENTS.
S. D. Morrison. 10s. 6d. 1952.

Orders and remittances should be sent to: COMMONWEALTH AGRICULTURAL BUREAUX,
CENTRAL SALES BRANCH, Farnham Royal, Bucks., England.

Nutrition Abstracts and Reviews

REVIEW ARTICLES reprinted from Nutrition Abstracts and Reviews

Price 1s. each except where a special price is given

(Those marked with an asterisk are out of print.)

DIET AND DENTAL DISEASE. S. J. Cowell, 1936, 5, 567.

*A REVIEW OF RECENT WORK ON DIETARY REQUIREMENTS IN PREGNANCY AND LACTATION, WITH AN ATTEMPT TO ASSESS HUMAN REQUIREMENTS. R. C. Garry and D. Stiven, 1936, 5, 855.

AN ANALYSIS AND COMPARISON OF DIFFERENT METHODS OF CALCULATING THE ENERGY VALUE OF DIETS. N. B. Morey, 1936, 6, 1.

THE PROTEIN REQUIREMENTS OF LACTATION. S. Morris, 1936, 6, 273.

THE DETERMINATION OF THE CALCIUM REQUIREMENTS OF MAN. I. Leitch, 1937, 6, 553; 1938, 8, 1.

THE RELATIVE POTENCY OF VITAMIN D FROM DIFFERENT SOURCES. E. M. Hume, 1937, 6, 891.

NUTRITIONAL SCIENCE AND ITS SOCIAL ASPECTS. Sir Richard Gregory, Bart., 1937, 7, 1.

THE DETERMINATION OF THE PROTEIN REQUIREMENTS OF MAN. I. Leitch and J. Duckworth, 1937, 7, 257.

THE DETERMINATION OF THE CALORIE REQUIREMENTS OF MAN. J. B. Orr and I. Leitch, 1938, 7, 509.

RECENT RESEARCH ON VITAMIN E. A. L. Bacharach, 1938, 7, 811.

*TABLES OF THE VITAMIN CONTENT OF HUMAN AND ANIMAL FOODS. M. A. B. Fixsen and M. H. Roscoe, 1938, 7, 823.

*THE VITAMIN CONTENT OF HUMAN FOODS AS AFFECTED BY PROCESSES OF COOKING AND CANNING (with tables). M. A. B. Fixsen, 1938, 8, 281.

THE NUTRITIVE VALUE OF WHEATEN FLOUR AND BREAD. A. M. Copping, 1939, 8, 555.

MAGNESIUM IN ANIMAL NUTRITION. J. Duckworth, 1939, 8, 841.

PASTEURISATION OF MILK: SOME RECENT ASPECTS. H. D. Kay, 1939, 9, 1.

CHRONIC FLUORINE INTOXICATION IN DOMESTIC ANIMALS. A. W. Peirce, 1939, 9, 253.

*THE SIGNIFICANCE OF THE "TRACE ELEMENTS" IN NUTRITION. E. J. Underwood, 1940, 9, 515.

TABLES OF THE VITAMIN CONTENT OF HUMAN AND ANIMAL FOODS. M. A. B. Fixsen and M. H. Roscoe, 1940, 9, 795. Price 2s. 6d.

QUALITY AND QUANTITY OF PROTEIN IN RELATION TO HUMAN HEALTH AND DISEASE. D. P. Cuthbertson, 1940, 10, 1.

VITAMIN A DEFICIENCY AND REQUIREMENTS OF FARM MAMMALS. G. H. Hart, 1940, 10, 261.

THE DISTRIBUTION OF NICOTINIC ACID IN HUMAN AND ANIMAL FOODS. A. L. Bacharach, 1941, 10, 459.

THE EFFECT OF DIET ON THE CHEMICAL COMPOSITION, NUTRITIVE VALUE AND HATCHABILITY OF THE EGG. E. M. Cruickshank, 1941, 10, 645.

NUTRITION AND HUMAN WELFARE. J. B. Orr, 1941, 11, 3.

INDIAN DIETS AND THEIR IMPROVEMENT. W. R. Aykroyd, 1941, 11, 171.

COMPONENTS OF THE VITAMIN B₂ COMPLEX. S. Lepkovsky, 1942, 11, 363.

THE EVOLUTION OF DIETARY STANDARDS. I. Leitch, 1942, 11, 509.

CHOLESTEROL METABOLISM. R. P. Cook, 1942, 12, 1.

THE MAGNESIUM REQUIREMENTS OF MAN IN RELATION TO CALCIUM REQUIREMENTS, WITH OBSERVATIONS ON THE ADEQUACY OF DIETS IN COMMON USE. J. Duckworth and G. M. Warnock, 1942, 12, 167.

THE ROLE OF VITAMIN CONCENTRATES IN WAR AND IN POST-WAR FOOD RELIEF IN EUROPE. V. P. Sydenstricker, 1943, 12, 339.

SOME PECULIARITIES OF RUMINANT NUTRITION. H. Goss, 1943, 12, 531.

THE PRESERVATION OF FOOD. Sir J. Barcroft, 1943, 13, 1.

*SOME CAUSES OF VARIATION IN THE VITAMIN CONTENT OF PLANTS GROWN FOR FOOD. L. A. Maynard and K. C. Beeson, 1943, 13, 155.

THE NUTRITIONAL REQUIREMENTS OF THE DOG. L. Michaud and C. A. Elvehjem, 1944, 13, 323.

PROTEIN HYDROLYSATES IN INTRAVENOUS ALIMENTATION. W. E. Gaunt, 1944, 13, 501.

NUCLEIC ACIDS AND TISSUE GROWTH. J. N. Davidson and C. Waymouth, 1944, 14, 1.

*THE WATER ECONOMY OF FARM ANIMALS. I. Leitch and J. S. Thomson, 1944, 14, 197.

SOME ASPECTS OF RIBOFLAVIN NUTRITION IN MAN. A. M. Copping, 1945, 14, 433.

*THE REQUIREMENT FOR CALCIUM DURING GROWTH. J. O. Holmes, 1945, 14, 597.

*THE STORAGE OF PROTEIN IN THE ADULT ANIMAL. H. W. Kosterlitz and R. M. Campbell, 1945, 15, 1.

*DIETARY DEFICIENCIES AND ENERGY METABOLISM. M. Kleiber, 1945, 15, 207.

THE AMOUNTS OF VITAMIN B₁ IN CEREALS AND THE EXTENT TO WHICH THEY SUPPLY HUMAN REQUIREMENTS IN VARIOUS DIETARIES. W. I. M. Holman, 1946, 15, 387. Price 2s. 6d.

DIETARY REQUIREMENTS IN HUMAN PREGNANCY AND LACTATION. A REVIEW OF RECENT WORK. R. C. Garry and H. O. Wood, 1946, 15, 591. Price 3s. 6d.

THE VITAMIN REQUIREMENTS OF SWINE. N. R. Ellis, 1946, 16, 1.

*THE CORRELATION OF THE AMINO-ACID COMPOSITION OF PROTEINS WITH THEIR NUTRITIVE VALUE. R. J. Block and H. H. Mitchell, 1946, 16, 249. Price 3s. 6d.

MICROBIOLOGICAL METHODS FOR THE ESTIMATION OF AMINO-ACIDS. B. S. Schweigert and E. S. Snell, 1947, 16, 497. Price 2s. 6d.

*PRODUCTION AND MODIFICATION OF LIVER DISEASE BY DIET. L. E. Glynn, 1947, 16, 751.

*THE ROLE OF THE MICROFLORA OF THE ALIMENTARY TRACT OF HERBIVORA WITH SPECIAL REFERENCE TO RUMINANTS. F. Baker, S. T. Hattiss, A. T. Phillipson, M. L. McNaught, J. A. B. Smith, S. K. Kon and J. W. G. Porter, 1947, 17, 1. Price 4s.

REVIEW ARTICLES reprinted from Nutrition Abstracts and Reviews (continued)

- THE VALUE OF CAPILLARY STRENGTH TESTS IN THE DIAGNOSIS OF VITAMIN C AND VITAMIN P DEFICIENCY IN MAN. H. N. Munro, S. Lazariis and G. H. Bell, 1947, 17, 231. Price 2s.
- THE INFLUENCE OF DIET ON PARODONTAL DISEASE. J. D. King, 1948, 17, 569. Price 2s. 6d.
- METHODS OF ESTIMATING PLASMA AND TOTAL RED CELL VOLUME. E. B. Reeve, 1948, 17, 811. Price 2s.
- *THE NUTRITIVE VALUE OF SILAGE AND DRIED GRASS. S. J. Watson, 1948, 18, 1. Price 1s. 6d.
- *THE EFFECT OF MILLING UPON THE NUTRITIVE VALUE OF WHEATEN FLOUR AND BREAD. M. C. Dawbarn, 1949, 18, 691. Price 2s.
- THE CALORIE REQUIREMENT OF ADULT MAN. Ancel Keys, 1949, 19, 1.
- THE MINERAL REQUIREMENTS AND METABOLISM OF POULTRY. Cyril Tyler, 1948, 18, 261, 473; 1949, 19, 263. Price 6s.
- TECHNIQUE AND INTERPRETATION OF DIETARY SURVEYS. I. Leitch and F. C. Aitken, 1950, 19, 507.
- THE VITAMIN REQUIREMENTS OF POULTRY. A. S. Hogan, 1950, 19, 751. Price 6s.
- ENERGY FEEDING STANDARDS FOR DAIRY CATTLE. K. L. Blaxter, 1950, 20, 1. Price 3s.
- EVALUATION OF LEANNESS-FATNESS IN MAN: A SURVEY OF METHODS. J. Brozek and Ancel Keys, 1950, 20, 247. Price 2s.
- THE CAUSATION OF PELLAGRA. Harriette Chick, 1951, 20, 523. Price 2s.
- *VITAMIN B₁₂. PART I. E. Lester Smith, 1951, 20, 795. Price 2s.
- VITAMIN B₁₂. PART II. A REVIEW OF THE CLINICAL ASPECTS. C. C. Ungley, 1951, 21, 1. Price 4s.
- EXPANSION OF LIVESTOCK PRODUCTION IN RELATION TO HUMAN NEEDS. Ralph W. Phillips, 1951, 21, 241. Price 2s.
- THE METABOLISM OF FAT IN THE MAMMARY GLAND AND FOETAL TISSUES, WITH REFERENCE TO THE APPLICATION OF ISOTOPIC TRACERS. G. Popják, 1952, 21, 535. Price 2s. 6d.
- THE FLUORINE PROBLEM IN LIVESTOCK FEEDING. H. H. Mitchell and Marjorie Edman, 1952, 21, 787. Price 2s.
- VITAMIN E IN THE NUTRITION OF FARM ANIMALS. K. L. Blaxter and F. Brown, 1952, 22, 1. Price 2s. 6d.
- MEAL HABITS AND THEIR EFFECTS ON PERFORMANCE. R. C. Hutchinson, 1952, 22, 283. Price 2s.
- THE STORAGE OF ELEMENTS IN THE SKELETON. J. Duckworth and R. Hill, 1953, 23, 1. Price 2s.
- FAO. W. R. Aykroyd, 1953, 23, 229. Price 2s.
- ANTIBIOTICS IN NUTRITION. R. Braude, S. K. Kon and J. W. G. Porter, 1953, 23, 473. Price 3s.
- NUTRITION AND HOST-HELMINTH RELATIONSHIPS. G. C. Hunter, 1953, 23, 705. Price 2s.
- THE DIAGNOSIS OF MALNUTRITION IN MAN. A. M. Thomson and D. L. Duncan, 1954, 24, 1. Price 3s.
- SECULAR CHANGE IN THE HEIGHT OF BRITISH ADULTS. A. W. Boyne and I. Leitch, 1954, 24, 255. Price 2s.
- THE SEA AND WORLD FOOD SUPPLIES. D. B. Finn, 1954, 24, 487. Price 2s.
- LAND USE AND DEVELOPMENT IN AUSTRALIA. C. G. Stephens, 1954, 24, 731. Price 2s.
- THE NUTRITION OF THE HORSE. N. Olsson and A. Ruudvere, 1955, 25, 1. Price 3s. 6d.
- THE PHYSIOLOGICAL EFFECTS OF LACTOSE. D. L. Duncan, 1955, 25, 309. Price 2s.

When ordering please quote authors' names and dates: e.g., *Morey* (1936); *Fixsen and Roscoe* (1940).
Orders and remittances should be sent to: THE SECRETARY, "NUTRITION ABSTRACTS AND REVIEWS,"
Rowett Institute, Bucksburn, Aberdeenshire, Scotland.

MEDICAL RESEARCH COUNCIL

STUDIES ON EXPENDITURE OF ENERGY AND CONSUMPTION OF FOOD BY MINERS AND CLERKS, FIFE, SCOTLAND, 1952

by

R. C. GARRY, R. PASSMORE, GRACE M. WARNOCK AND J. V. G. A. DURNIN

Special Report Series No. 289

5s. net; by post, 5s. 3d.

The publications of the Medical Research Council can be obtained from the following sources:—

LONDON: H.M. STATIONERY OFFICE, YORK HOUSE, KINGSWAY, W.C.2; 423 OXFORD STREET, W.1
(or P.O. BOX 569, S.E.1)

NEW YORK: BRITISH INFORMATION SERVICES, 30 ROCKEFELLER PLAZA

Through booksellers in any country

RESEARCH JOURNALS

PUBLISHED BY

NATIONAL RESEARCH COUNCIL OF CANADA

Under the authority of the Chairman of the Committee of the Privy Council on Scientific and Industrial Research, the National Research Council issues seven journals devoted to the publication of the results of original scientific research. Most of the research on which the papers are based is carried out in Canada, but contributions from workers in other countries are accepted also. Papers are published in English or French.

The seven journals, their frequency of publication, and the annual subscription rates are :—

Canadian Journal of Biochemistry and Physiology (formerly <i>Canadian Journal of Medical Sciences</i>)	Bi-monthly	\$3.00
Canadian Journal of Botany	Bi-monthly	\$4.00
Canadian Journal of Chemistry	Monthly	\$5.00
Canadian Journal of Microbiology	Bi-monthly	\$3.00
Canadian Journal of Physics	Monthly	\$4.00
Canadian Journal of Technology	Bi-monthly	\$3.00
Canadian Journal of Zoology	Bi-monthly	\$3.00

Volume I of the "Canadian Journal of Microbiology" will consist of 9 numbers, i.e., August, 1954, to December, 1955.

Manuscripts for consideration should be submitted to the Editor-in-Chief, National Research Council, Ottawa, Canada.

Requests for subscriptions should be mailed to the National Research Council, Ottawa 2, Canada, and remittances made payable to the Receiver General of Canada, credit National Research Council.

The British Journal of NUTRITION

Vol. 9, No. 3, 1955. 30s. net

- H. B. N. MURTHY, SARANYA KUMARI REDDY, M. SWAMINATHAN and V. SUBRAHMANYAN. The metabolism of nitrogen, calcium and phosphorus in undernourished children. 1. Adaptation to low intake of calories, protein, calcium and phosphorus.
- GOWRI SUR, SARANYA KUMARI REDDY, M. SWAMINATHAN and V. SUBRAHMANYAN. 2. The effect of supplementary groundnut-milk curds on the metabolism of nitrogen, calcium and phosphorus.
- D. LEWIS. Amino-acid metabolism in the rumen of the sheep.
- RUTH SCHWARTZ and R. F. A. DEAN. An investigation of the daily intakes of food by individual boys at a boarding school in Uganda.
- S. K. KOK, W. A. MCGILLIVRAY and S. Y. THOMPSON. Metabolism of carotene and vitamin A given by mouth or vein in oily solution or aqueous dispersion to calves, rabbits and rats.
- I. A. M. LUCAS and A. F. C. CALDER. Thyroxine, stilboestrol and antibiotics in rations for castrated male pigs.
- D. E. WRIGHT. Fat in liver and kidneys of pregnant sheep at different levels of nutrition and during starvation.
- O. G. EDHOLM, J. G. FLETCHER, ELSIE M. WIDDOWSON and R. A. McCANCE. The energy expenditure and food intake of individual men.
- J. T. IRVING and O. E. BUDTZ-OLSEN. The relation between the action of vitamin E and protein in the body, and the influence of various fish-liver oils in the diet upon vitamin E activity in vivo.
- L. J. HARRIS, B. J. CONSTABLE, R. E. HUGHES and G. LOEWI. Influence of cortisone on ascorbic-acid requirements of guinea-pigs: an assessment by the tooth-structure method.
- ELsie M. WIDDOWSON and R. A. McCANCE. Physiological undernutrition in the newborn guinea-pig.

Published for The Nutrition Society by the Cambridge University Press, Bentley House, 200 Euston Road, N.W.1. The combined subscription for *The British Journal of Nutrition* (4 parts a year) and *The Proceedings of the Nutrition Society* (2 parts a year) is £6. Single issues of either publication are 30s. each, plus postage.

Zentralblatt für Veterinärmedizin

Prof. Dr. M. LERCHE
Free University, Berlin

Edited by
and

Prof. Dr. H. SPÖRRI
University, Zürich

with the collaboration of many scientists of international repute

The *Zentralblatt für Veterinärmedizin* is an international journal which publishes the results of research in all branches of veterinary medicine. The journal provides the several disciplines of veterinary medicine with information on current aims and results in all the fields of research; it offers the information also to allied sciences so that a fruitful interchange of knowledge and ideas may develop.

Original papers appear in German, English, French or Spanish with summaries in all four languages.

In scope and volume the *Zentralblatt* exceeds other journals of veterinary medicine and in the presentation and value of the papers published is comparable with the best journals serving other sciences.

There are annually 6 parts each of 6 or 7 sheets. The parts of one calendar year form a volume.
Price per sheet (16 pages) about DM. 3. Each part is priced separately.

Zeitschrift für Tierzüchtung und Züchtungsbiologie

Founded in 1924 by C. KRONACHER

Edited by Prof. Dr. J. SCHMIDT
with the collaboration of many international authorities

This journal is the recognised international organ for research on all branches of animal breeding, the biology of animal production and related subjects: racial biology, evolution, genetics, development, growth, constitution and adaptation; osteology and the mechanics of the skeleton, animal nutrition and animal hygiene.

It provides for all technical experts, veterinary officers and biologists a valuable survey of current research.

There are annually about 6 parts and 4 parts are a volume. A part is of about 6 sheets.
Price per sheet of 16 pages about DM. 4. Each part is separately priced.

Published by PAUL PAREY, Lindenstr. 44/47, Berlin, S.W.68 (Westberlin)

FOOD SCIENCE ABSTRACTS

A bi-monthly journal of abstracts and reviews
giving scientific and technical information about the processing,
storage and transport, and the behaviour, properties,
composition and quality of foods

It is divided into sections on: meat; poultry and game; fish and shellfish; eggs; dairy produce; fats and oils; fruits and vegetables; cereal grains, pulses, nuts, animal feeding-stuffs, etc.; sugar, syrup, confectionery, tea, coffee, cocoa, spices, flavours, condiments; general processing and chemical engineering; physics and refrigerating engineering; packaging methods and materials and miscellaneous.

EACH ANNUAL VOLUME CONTAINS OVER 3,000 ABSTRACTS,
AND A SUBJECT AND AUTHOR INDEX

Review articles published in 1954 included the following:—

“The Preservation of Foods with Ionizing Radiations.”

“Chemicals and Food.”

“Dehydrofreezing of Fruits and Vegetables.”

“The Bacterial Contamination of Foods.”

FOOD SCIENCE ABSTRACTS is prepared by the Food Investigation Organization of the Department of Scientific and Industrial Research, and is published by H.M. Stationery Office. It may be purchased direct from H.M. Stationery Office at the following addresses or through any bookseller:—

York House, Kingsway, London, W.C.2; 423 Oxford Street, London, W.1;
(Post Orders—P.O. Box No. 569, London, S.E.1); 13a Castle Street, Edinburgh, 2;
39 King Street, Manchester, 2; 2 Edmund Street, Birmingham, 3; 1 St. Andrew's
Crescent, Cardiff; Tower Lane, Bristol, 1; 80 Chichester Street, Belfast.

Subscription Rates for 1955

Annual subscription (including index)	£4 including postage
Per number	12s. 6d. (by post 12s. 10d.)
Annual index	12s. 6d. (by post 12s. 10d.)
20 per cent. reduction for bulk orders of 100 copies or more	

Correspondence should be addressed to:—

THE EDITOR, FOOD SCIENCE ABSTRACTS
DIRECTORATE OF FOOD INVESTIGATION, D.S.I.R.
20A REGENT STREET, CAMBRIDGE

AUTHOR INDEX

* Nomenclature of Amino-Acids

In *Review Articles* it will be that agreed upon by the Editors of the *Journal of the Chemical Society* and of the *Biochemical Journal* published in *Biochem. J.*, 1948, 42, 1.

In *Abstracts* the nomenclature will be that used in the paper being abstracted.

TECHNICAL COMMUNICATIONS

Price 1s. each except those otherwise marked

- No. 11. SPROUTED FODDER AND GERMINATED GRAIN IN STOCK FEEDING. I. Leitch,
M.A., D.Sc. 1939.
- No. 14. THE EFFICIENCY OF FARM ANIMALS IN THE CONVERSION OF FEEDINGSTUFFS
TO FOOD FOR MAN. (Mimeographic reproduction with addendum) I. Leitch
and W. Godden. 5s. 1953.
- No. 16. DIET IN RELATION TO REPRODUCTION AND THE VIABILITY OF THE YOUNG.
PART I.: RATS AND OTHER LABORATORY ANIMALS. F. C. Russell, B.Sc. 6s.
1948.
- No. 17. STATISTICAL STUDIES OF RECORDED ENERGY EXPENDITURE OF MAN. PART I:
BASAL METABOLISM RELATED TO SEX, STATURE, AGE, CLIMATE AND RACE.
M. H. Quenouille, A. W. Boyne, W. B. Fisher and I. Leitch. 6s. 1951.
- No. 18. HUMAN MILK. YIELD, PROXIMATE PRINCIPLES AND INORGANIC CONSTITUENTS.
S. D. Morrison. 10s. 6d. 1952.

Orders and remittances should be sent to: COMMONWEALTH AGRICULTURAL BUREAUX,
CENTRAL SALES BRANCH, Farnham Royal, Bucks., England.

Nutrition Abstracts and Reviews

REVIEW ARTICLES reprinted from Nutrition Abstracts and Reviews

Price 1s. each except where a special price is given
(Those marked with an asterisk are out of print.)

- DIET AND DENTAL DISEASE. S. J. Cowell, 1936, 5, 567.
- *A REVIEW OF RECENT WORK ON DIETARY REQUIREMENTS IN PREGNANCY AND LACTATION, WITH AN ATTEMPT TO ASSESS HUMAN REQUIREMENTS. R. C. Garry and D. Silver, 1936, 5, 855.
- AN ANALYSIS AND COMPARISON OF DIFFERENT METHODS OF CALCULATING THE ENERGY VALUE OF DIETS. N. B. Morey, 1936, 6, 1.
- THE PROTEIN REQUIREMENTS OF LACTATION. S. Morris, 1936, 6, 273.
- THE DETERMINATION OF THE CALCIUM REQUIREMENTS OF MAN. I. Leitch, 1937, 6, 553; 1938, 8, 1.
- THE RELATIVE POTENCY OF VITAMIN D FROM DIFFERENT SOURCES. E. M. Hume, 1937, 6, 891.
- NUTRITIONAL SCIENCE AND ITS SOCIAL ASPECTS. Sir Richard Gregory, Bart., 1937, 7, 1.
- THE DETERMINATION OF THE PROTEIN REQUIREMENTS OF MAN. I. Leitch and J. Duckworth, 1937, 7, 257.
- THE DETERMINATION OF THE CALORIE REQUIREMENTS OF MAN. J. B. Orr and I. Leitch, 1938, 7, 509.
- RECENT RESEARCH ON VITAMIN E. A. L. Bacharach, 1938, 7, 811.
- *TABLES OF THE VITAMIN CONTENT OF HUMAN AND ANIMAL FOODS. M. A. B. Fixsen and M. H. Roscoe, 1938, 7, 823.
- *THE VITAMIN CONTENT OF HUMAN FOODS AS AFFECTED BY PROCESSES OF COOKING AND CANNING (with tables). M. A. B. Fixsen, 1938, 8, 261.
- THE NUTRITIVE VALUE OF WHEATEN FLOUR AND BREAD. A. M. Copping, 1939, 8, 555.
- MAGNESIUM IN ANIMAL NUTRITION. J. Duckworth, 1939, 8, 841.
- PASTEURISATION OF MILK: SOME RECENT ASPECTS. H. D. Kay, 1939, 9, 1.
- CHRONIC FLUORINE INTOXICATION IN DOMESTIC ANIMALS. A. W. Pirnce, 1939, 9, 253.
- *THE SIGNIFICANCE OF THE "TRACE ELEMENTS" IN NUTRITION. E. J. Underwood, 1940, 9, 515.
- TABLES OF THE VITAMIN CONTENT OF HUMAN AND ANIMAL FOODS. M. A. B. Fixsen and M. H. Roscoe, 1940, 9, 795. Price 2s. 6d.
- QUALITY AND QUANTITY OF PROTEIN IN RELATION TO HUMAN HEALTH AND DISEASE. D. P. Cuthbertson, 1940, 10, 1.
- VITAMIN A DEFICIENCY AND REQUIREMENTS OF FARM MAMMALS. G. H. Hart, 1940, 10, 261.
- THE DISTRIBUTION OF NICOTINIC ACID IN HUMAN AND ANIMAL FOODS. A. L. Bacharach, 1941, 10, 459.
- THE EFFECT OF DIET ON THE CHEMICAL COMPOSITION, NUTRITIVE VALUE AND HATCHABILITY OF THE EGG. E. M. Cruickshank, 1941, 10, 645.
- NUTRITION AND HUMAN WELFARE. J. B. Orr, 1941, 11, 3.
- INDIAN DIETS AND THEIR IMPROVEMENT. W. R. Aykroyd, 1941, 11, 171.
- COMPONENTS OF THE VITAMIN B₂ COMPLEX. S. Lepkovsky, 1942, 11, 383.
- THE EVOLUTION OF DIETARY STANDARDS. I. Leitch, 1942, 11, 509.
- CHOLESTEROL METABOLISM. R. P. Cook, 1942, 12, 1.
- THE MAGNESIUM REQUIREMENTS OF MAN IN RELATION TO CALCIUM REQUIREMENTS, WITH OBSERVATIONS ON THE ADEQUACY OF DIETS IN COMMON USE. J. Duckworth and G. M. Warnock, 1942, 12, 167.
- THE RÔLE OF VITAMIN CONCENTRATES IN WAR AND IN POST-WAR FOOD RELIEF IN EUROPE. V. P. Sydenstricker, 1943, 12, 339.
- SOME PECULIARITIES OF RUMINANT NUTRITION. H. Goss, 1943, 12, 531.
- THE PRESERVATION OF FOOD. Sir J. Barcroft, 1943, 13, 1.
- *SOME CAUSES OF VARIATION IN THE VITAMIN CONTENT OF PLANTS GROWN FOR FOOD. L. A. Maynard and K. C. Beeson, 1943, 13, 155.
- THE NUTRITIONAL REQUIREMENTS OF THE DOG. L. Michaud and C. A. Elvehjem, 1944, 13, 323.
- PROTEIN HYDROLYSATES IN INTRAVENOUS ALIMENTATION. W. E. Gaunt, 1944, 13, 501.
- NUCLEIC ACIDS AND TISSUE GROWTH. J. N. Davidson and C. Waymouth, 1944, 14, 1.
- *THE WATER ECONOMY OF FARM ANIMALS. I. Leitch and J. S. Thomson, 1944, 14, 197.
- SOME ASPECTS OF RIBOFLAVIN NUTRITION IN MAN. A. M. Copping, 1945, 14, 433.
- *THE REQUIREMENT FOR CALCIUM DURING GROWTH. J. O. Holmes, 1945, 14, 597.
- *THE STORAGE OF PROTEIN IN THE ADULT ANIMAL. H. W. Kosterlitz and R. M. Campbell, 1945, 15, 1.
- *DIETARY DEFICIENCIES AND ENERGY METABOLISM. M. Kleiber, 1945, 15, 207.
- THE AMOUNTS OF VITAMIN B₁ IN CEREALS AND THE EXTENT TO WHICH THEY SUPPLY HUMAN REQUIREMENTS IN VARIOUS DIETARIES. W. I. M. Holman, 1946, 15, 387. Price 2s. 6d.
- DIETARY DEFICIENCIES IN HUMAN PREGNANCY AND LACTATION. A REVIEW OF RECENT WORK. R. C. Garry and H. O. Wood, 1946, 15, 591. Price 3s. 6d.
- THE VITAMIN REQUIREMENTS OF SWINE. N. R. Ellis, 1946, 16, 1.
- *DISTRIBUTION OF THE AMINO-ACID COMPOSITION OF PROTEINS WITH THEIR NUTRITIVE VALUE. R. J. Block and H. H. Mitchell, 1946, 16, 249. Price 3s. 6d.
- MICROBIOLOGICAL METHODS FOR THE ESTIMATION OF AMINO-ACIDS. B. S. Schweigert and E. S. Snell, 1947, 16, 497. Price 2s. 6d.
- *PRODUCTION AND MODIFICATION OF LIVER DISEASE BY DIET. L. E. Glynn, 1947, 16, 751.
- *THE RÔLE OF THE MICROFLORA OF THE ALIMENTARY TRACT OF HERBIVORA WITH SPECIAL REFERENCE TO RUMINANTS. F. Baker, S. T. Hartiss, A. T. Phillipson, M. L. McNaught, J. A. B. Smith, S. K. Kon and J. W. G. Porter, 1947, 17, 1. Price 4s.

REVIEW ARTICLES reprinted from Nutrition Abstracts and Reviews (continued)

- THE VALUE OF CAPILLARY STRENGTH TESTS IN THE DIAGNOSIS OF VITAMIN C AND VITAMIN P DEFICIENCY IN MAN. H. N. Munro, S. Lazarus and C. H. Bell, 1947, 17, 291. Price 2s.
- THE INFLUENCE OF DIET ON PARODONTAL DISEASE. J. D. King, 1948, 17, 589. Price 2s. 6d.
- METHODS OF ESTIMATING PLASMA AND TOTAL RED CELL VOLUME. E. B. Reeve, 1948, 17, 811. Price 2s.
- *THE NUTRITIVE VALUE OF SILAGE AND DRIED GRASS. S. J. Watson, 1948, 18, 1. Price 1s. 6d.
- *THE EFFECT OF MILLING UPON THE NUTRITIVE VALUE OF WHEATEN FLOUR AND BREAD. M. C. Dawbarn, 1949, 18, 691. Price 2s.
- THE CALORIE REQUIREMENT OF ADULT MAN. Ancel Keys, 1949, 19, 1.
- THE MINERAL REQUIREMENTS AND METABOLISM OF POULTRY. Cyril Tyler, 1948, 18, 261, 473; 1949, 19, 263. Price 6s.
- TECHNIQUE AND INTERPRETATION OF DIETARY SURVEYS. I. Leitch and F. C. Aitken, 1950, 19, 507.
- THE VITAMIN REQUIREMENTS OF POULTRY. A. S. Hogan, 1950, 19, 751. Price 6s.
- ENERGY FEEDING STANDARDS FOR DAIRY CATTLE. K. L. Blaxter, 1950, 20, 1. Price 3s.
- EVALUATION OF LEANNESS-FATNESS IN MAN: A SURVEY OF METHODS. J. Brožek and Ancel Keys, 1950, 20, 247. Price 2s.
- THE CAUSATION OF PELLAGRA. Harriette Chick, 1951, 20, 523. Price 2s.
- *VITAMIN B₁₂. PART I. E. Lester Smith, 1951, 20, 795. Price 2s.
- VITAMIN B₁₂. PART II. A REVIEW OF THE CLINICAL ASPECTS. C. C. Ungley, 1951, 21, 1. Price 4s.
- EXPANSION OF LIVESTOCK PRODUCTION IN RELATION TO HUMAN NEEDS. Ralph W. Phillips, 1951, 21, 241. Price 2s.
- THE METABOLISM OF FAT IN THE MAMMARY GLAND AND FOETAL TISSUES, WITH REFERENCE TO THE APPLICATION OF ISOTOPIC TRACERS. G. Popják, 1952, 21, 535. Price 2s. 6d.
- THE FLUORINE PROBLEM IN LIVESTOCK FEEDING. H. H. Mitchell and Marjorie Edman, 1952, 21, 787. Price 2s.
- VITAMIN E IN THE NUTRITION OF FARM ANIMALS. K. L. Blaxter and F. Brown, 1952, 22, 1. Price 2s. 6d.
- MEAL HABITS AND THEIR EFFECTS ON PERFORMANCE. R. C. Hutchinson, 1952, 22, 283. Price 2s.
- THE STORAGE OF ELEMENTS IN THE SKELETON. J. Duckworth and R. Hill, 1953, 23, 1. Price 2s.
- FAO. W. R. Aykroyd, 1953, 23, 229. Price 2s.
- ANTIBIOTICS IN NUTRITION. R. Braude, S. K. Kon and J. W. G. Porter, 1953, 23, 473. Price 3s.
- NUTRITION AND HOST-HELMINTH RELATIONSHIPS. G. C. Hunter, 1953, 23, 705. Price 2s.
- THE DIAGNOSIS OF MALNUTRITION IN MAN. A. M. Thomson and D. L. Duncan, 1954, 24, 1. Price 3s.
- SECULAR CHANGE IN THE HEIGHT OF BRITISH ADULTS. A. W. Boyne and I. Leitch, 1954, 24, 255. Price 2s.

- THE NUTRITION OF THE HORSE. N. Olsson and A. Ruudvere, 1955, 25, 1. Price 3s. 6d.
- THE PHYSIOLOGICAL EFFECTS OF LACTOSE. D. L. Duncan, 1955, 25, 309. Price 2s.
- THE PHYSIOLOGICAL BASIS OF OBESITY AND LEANNESS. J. Mayer, 1955, 25, 597; 871. Price 4s.

When ordering please quote authors' names and dates: e.g., Morey (1936); Fixsen and Roscoe (1940).
Orders and remittances should be sent to: THE SECRETARY, "NUTRITION ABSTRACTS AND REVIEWS,"
Rowett Institute, Bucksburn, Aberdeenshire, Scotland.

MEDICAL RESEARCH COUNCIL

STUDIES ON THE NUTRITIVE VALUE OF BREAD AND ON THE EFFECT OF VARIATIONS IN THE EXTRACTION RATE OF FLOUR ON THE GROWTH OF UNDERNOURISHED CHILDREN

by

E. M. WIDDOWSON AND R. A. MCCANCE

Special Report Series No. 287

8s. 6d. net; by post, 8s. 10d.

The publications of the Medical Research Council can be obtained from the following sources:—
LONDON: H.M. STATIONERY OFFICE, YORK HOUSE, KINGSWAY, W.C.2; 423 OXFORD STREET, W.1
(or P.O. Box 569, S.E.1)

NEW YORK: BRITISH INFORMATION SERVICES, 30 ROCKEFELLER PLAZA

Through booksellers in any country

RESEARCH JOURNALS

PUBLISHED BY

NATIONAL RESEARCH COUNCIL OF CANADA

Under the authority of the Chairman of the Committee of the Privy Council on Scientific and Industrial Research, the National Research Council issues seven journals devoted to the publication of the results of original scientific research. Most of the research on which the papers are based is carried out in Canada, but contributions from workers in other countries are accepted also. Papers are published in English or French.

The seven journals, their frequency of publication, and the annual subscription rates are:—

Canadian Journal of Biochemistry and Physiology (formerly <i>Canadian Journal of Medical Sciences</i>)	Bi-monthly	\$3.00
Canadian Journal of Botany	Bi-monthly	\$4.00
Canadian Journal of Chemistry	Monthly	\$5.00
Canadian Journal of Microbiology	Bi-monthly	\$3.00
Canadian Journal of Physics	Monthly	\$4.00
Canadian Journal of Technology	Bi-monthly	\$3.00
Canadian Journal of Zoology	Bi-monthly	\$3.00

Volume 1 of the "Canadian Journal of Microbiology" will consist of 9 numbers, i.e., August, 1954, to December, 1955.

Manuscripts for consideration should be submitted to the Editor-in-Chief, National Research Council, Ottawa, Canada.

Requests for subscriptions should be mailed to the National Research Council, Ottawa 2, Canada, and remittances made payable to the Receiver General of Canada, credit National Research Council.

The British Journal of NUTRITION

Vol. 9, No. 4, 1955. 30s. net

GWYNETH M. CHAPPELL. Long-term individual dietary surveys.

HANS FISHER, H. M. SCOTT and B. CONNOR JOHNSON. Quantitative aspects of the nicotinic acid-tryptophan inter-relationship in the chick.

V. SUBRAHMANYAN, M. NARAYANARAO, G. RAMARAO and M. SWAMINATHAN. The metabolism of nitrogen, calcium and phosphorus in human adults on a poor vegetarian diet containing ragi (*Eleusine coracana*).

R. J. BOWLER, R. BRAUDE, R. C. CAMPBELL, J. N. CRADDOCK-TURNBULL, H. F. FIELDSEND, E. K. GRIFFITHS, I. A. M. LUCAS, K. G. MITCHELL, N. J. D. NICKALLS and J. H. TAYLOR. High-copper mineral mixture for fattening pigs.

R. BRAUDE, MARIE E. COATES, MARY K. DAVIES, G. F. HARRISON and K. G. MITCHELL. The effect of aureomycin on the gut of the pig.

P. C. FENG and E. A. KEAN. Influence of diet on the acute toxicity of hypoglycin-A in rats.

B. P. HUGHES. The essential amino-acid intakes of children who were deriving most of their protein from bread and vegetables.

R. S. BARBER, R. BRAUDE and K. G. MITCHELL. Antibiotic and copper supplements for fattening pigs.

D. S. MILLER and A. E. BENDER. The determination of the net utilisation of proteins by a shortened method.

J. H. MOORE and C. TYLER. Studies on the intestinal absorption and excretion of calcium and phosphorus in the pig. 3. The effect of beryllium carbonate on the absorption of phosphorus.

C. F. MILLS. The availability of copper in freeze-dried herbage and herbage extracts to the copper-deficient rat.

Published for The Nutrition Society by the Cambridge University Press, Bentley House, 200 Euston Road, N.W.1. The combined subscription for *The British Journal of Nutrition* (4 parts a year) and *The Proceedings of the Nutrition Society* (2 parts a year) for 1956 is £7. Single issue of either publication are 35s. each, plus postage.

Zentralblatt für Veterinärmedizin

Prof. Dr. M. LERCHE
Free University, Berlin

Edited by
and

Prof. Dr. H. SPÖRRI
University, Zürich

with the collaboration of many scientists of international repute

The *Zentralblatt für Veterinärmedizin* is an international journal which publishes the results of research in all branches of veterinary medicine. The journal provides the several disciplines of veterinary medicine with information on current aims and results in all the fields of research; it offers the information also to allied sciences so that a fruitful interchange of knowledge and ideas may develop.

Original papers appear in German, English, French or Spanish with summaries in all four languages.

In scope and volume the *Zentralblatt* exceeds other journals of veterinary medicine and in the presentation and value of the papers published is comparable with the best journals serving other sciences.

There are annually 6 parts each of 6 or 7 sheets. The parts of one calendar year form a volume.
Price per sheet (16 pages) about DM. 3. Each part is priced separately.

Zeitschrift für Tierzüchtung und Züchtungsbiologie

Founded in 1924 by C. KRONACHER

Edited by Prof. Dr. J. SCHMIDT
with the collaboration of many international authorities

This journal is the recognised international organ for research on all branches of animal breeding, the biology of animal production and related subjects: racial biology, evolution, genetics, development, growth, constitution and adaptation; osteology and the mechanics of the skeleton, animal nutrition and animal hygiene.

It provides for all technical experts, veterinary officers and biologists a valuable survey of current research.

There are annually about 6 parts and 4 parts are a volume. A part is of about 6 sheets.
Price per sheet of 16 pages about DM. 4. Each part is separately priced.

Published by PAUL PAREY, Lindenstr. 44/47, Berlin, S.W.68 (Westberlin)

FOOD SCIENCE ABSTRACTS

A bi-monthly journal of abstracts and reviews giving scientific and technical information about the processing, storage and transport, and the behaviour, properties, composition and quality of foods

It is divided into sections on: meat; poultry and game; fish and shellfish; eggs; dairy produce; fats and oils; fruits and vegetables; cereal grains, pulses, nuts, animal feeding-stuffs, etc.; sugar, syrup, confectionery, tea, coffee, cocoa, spices, flavours, condiments; general processing and chemical engineering; physics and refrigerating engineering; packaging methods and materials; and miscellaneous.

EACH ANNUAL VOLUME CONTAINS OVER 3,000 ABSTRACTS,
AND A SUBJECT AND AUTHOR INDEX

Review articles published in 1954 included the following:—

- "The Preservation of Foods with Ionizing Radiations."
- "Chemicals and Food."
- "Dehydrofreezing of Fruits and Vegetables."
- "The Bacterial Contamination of Foods."

FOOD SCIENCE ABSTRACTS is prepared by the Food Investigation Organization of the Department of Scientific and Industrial Research, and is published by H.M. Stationery Office. It may be purchased direct from H.M. Stationery Office at the following addresses or through any bookseller:—

York House, Kingsway, London, W.C.2; 423 Oxford Street, London, W.1;
(Post Orders—P.O. Box No. 569, London, S.E.1); 13a Castle Street, Edinburgh, 2;
39 King Street, Manchester, 2; 2 Edmund Street, Birmingham, 3; 1 St. Andrew's
Crescent, Cardiff; Tower Lane, Bristol, 1; 80 Chichester Street, Belfast.

Subscription Rates for 1955

Annual subscription (including index) . . .	£4 including postage
Per number	12s. 6d. (by post 12s. 10d.)
Annual index	12s. 6d. (by post 12s. 10d.)

20 per cent. reduction for bulk orders of 100 copies or more

Correspondence should be addressed to:—

THE EDITOR, FOOD SCIENCE ABSTRACTS
DIRECTORATE OF FOOD INVESTIGATION, D.S.I.R.

Meat (all kinds)	910	Minerals	
Fish	910	GENERAL	1013
Other Types	911	CALCIUM AND PHOSPHORUS	1014
FOODSTUFFS OF VEGETABLE ORIGIN		MAGNESIUM	1017
General	911	SODIUM, POTASSIUM, AND SODIUM CHLORIDE	1017
Cereals	912	HALOGENS	1019
Roots	913	IRON AND COPPER	1021
Leafy Vegetables	913	OTHER MINERALS	1022
Legumes	913	Acid Base Equilibrium	1023
Fruits	913	Metabolism of Water	1024
Other Types	913	Metabolism of Other Substances	1024
Pasture, Hay and Silage	914	Metabolism of Cells, Tissues, etc.	
MISCELLANEOUS	916	GENERAL PHYSIOLOGY	1025
3. VITAMINS		GROWTH AND METABOLISM OF TUMOUR CELLS	1028
General	917	Metabolism of Growth, Reproduction and Senescence	
Vitamin A	919	GROWTH	1028
" D	926	REPRODUCTION AND LACTATION: MAMMALS	1031
" E	929	" : BIRDS	1034
" K	933	SENESCENCE	1035
" B Complex: General	934		
" B ₁ (Aneurin, Thiamine)	937		

TABLE OF CONTENTS

	PAGE		PAGE
Experimental Studies of Immunity and Micro-organisms	1037	GASTRO-INTESTINAL CONDITIONS	1076
Miscellaneous Feeding Experiments	1039	THYROID DISEASE	1078
General Metabolism and Feeding Habits of Animals other than Mammals and Birds	1043	ANAEMIA	1079
		OTHER CONDITIONS	1080
5. HUMAN DIET IN RELATION TO HEALTH AND DISEASE		6. FEEDING OF ANIMALS	
Diet		General, including Digestibility Trials	1083
REQUIREMENTS	1043	Horses	1089
FEEDING OF INFANTS AND CHILDREN	1044	Cattle	
DIETARY SURVEYS AND INDIVIDUAL STUDIES	1046	GROWTH AND FATTENING	1089
GENERAL STUDIES: DIET PLANNING: EDUCATION	1050	MILK PRODUCTION	1095
Food Economics and Statistics	1053	REPRODUCTION	1099
Diet in Etiology of Disease		Sheep	1099
METHODS OF ASSESSING STATE OF HEALTH	1054	Pigs	1104
GENERAL STUDIES	1054	Goats, Rabbits and other Mammals	1113
DEFICIENCY DISEASES		Poultry	
General	1056	GROWTH AND FATTENING	1115
Vitamin A	1059	EGG PRODUCTION	1123
D	1060	Other Birds	1125
E	1062	Food Economics and Statistics	1126
B Complex	1064	Diet in Etiology of Disease	
C	1071	GENERAL	1127
Other Vitamins	1072	DEFICIENCY DISEASES	1129
Other Elements	nil	DISEASES OF METABOLISM	1130
DENTAL DISEASES	1073	POISONS OCCURRING IN FOOD	1133
POISONS: PATHOGENIC ORGANISMS: FOOD LAWS	1074	MICRO-ORGANISMS OCCURRING IN FOOD	nil
IMMUNITY	nil	IMMUNITY	1135
Therapeutic and Preventive Dietetics		7. BOOK REVIEWS	1136
GENERAL	1074	8. FOOD AND AGRICULTURE ORGANIZATION OF THE UNITED NATIONS	1140
DIABETES	1075	9. DEPARTMENTAL AND OTHER REPORTS	1141

AUTHOR INDEX

* Nomenclature of Amino-Acids

In *Review Articles* it will be that agreed upon by the Editors of the *Journal of the Chemical Society* and of the *Biochemical Journal* published in *Biochem. J.*, 1948, 42, 1.

In *Abstracts* the nomenclature will be that used in the paper being abstracted.

INTRODUCTION

The rapid advance of mechanisation during the last 40 years has progressively reduced the use of horses for traction and for riding. The result has been a considerable reduction of the number of horses in many countries. The reduction in some European countries, the United States and Canada between 1912 and 1951 is shown in Table 1 (Institut International d'Agriculture, 1911-1912; 1922; 1931-1932; FAO 1947; 1952).

By 1951 the number of horses in the United States

had fallen to 22 per cent. of the number in 1912. In Canada the reduction in the same time was scarcely 50 per cent., and in Great Britain and Ireland about 59 per cent.

Table 2 gives data for the estimated number of horses in Europe, North and Central America and the whole world in 1939 and in the year 1950-51 (FAO, 1947; 1952).

From this it appears that the number of horses in North and Central America fell by considerably more, 39 per cent., than in Europe, 15 per cent.

THE NUTRITION OF THE HORSE

TABLE 1

NUMBER OF HORSES IN SOME EUROPEAN COUNTRIES, THE UNITED STATES AND CANADA BETWEEN 1912 AND 1951

Country	1912	1920	1930	1940	1951
Denmark	535,018	601,777	494,465 ¹	575,000 ¹	465,000
France	3,222,140	2,635,350	2,924,230	2,114,700 ²	2,397,000
Sweden	588,485	728,000	653,000	617,100	415,000
Great Britain and Ireland	2,058,565	2,213,053	1,669,672	1,508,600	845,000
United States	23,015,902	19,766,000 ¹	13,165,000 ¹	10,193,000 ¹	4,993,000 ¹
Canada	2,595,912	3,400,352	3,295,000	2,780,000 ¹	1,804,000 ¹

¹ Horses in towns not included.² Army horses not included.

In spite of the great decrease, there are still 61 million horses in the world. Even if agriculture and forestry are further mechanised so that their need for horses is further reduced, the horse will for long have some importance for traction, and it is for that reason that its correct feeding is still important.

TABLE 2

NUMBER OF HORSES IN EUROPE, NORTH AND CENTRAL AMERICA AND THE WORLD, IN MILLIONS

Year	Europe	North and Central America	Whole world
1939	19.9	18.0	74.4
1950/51	17.0	11.0	60.6

For a discussion on the physiology of digestion of the horse reference should be made to Alexander (1954).

Of published reports on the feeding of horses only a few are based on accurate experiments. Most have arisen from practical experience or from revision of older experiments.

DIGESTION IN HORSES AND RUMINANTS

Although the digestive system of the horse is unlike that of the ruminant in anatomical structure, both live on the same feedingstuffs and there is little difference in their capacity to digest them. The horse has a single stomach and does not ruminate; cattle have chambered stomachs and ruminate. Cattle also have longer and roomier intestines, as appears from the following comparison (Crasemann, 1945):

DIGESTIVE CANAL

Length (metres)		Volume (litres)		Distribution of volume (litres)		
Total	Ratio to body length	Total	Per 100 kg. liveweight	Stomach	Intestines total	Caecum
Horse 30	20 : 1	200	40	10	100	30
Cattle 50	30 : 1	310	50	200	110	10

The capacity of both to digest some of the feeds which appear most often in their diets is shown by the digestibility coefficients in Table 3 (Crasemann, 1945).

The organic matter in feedingstuffs of low fibre content, such as cereal grains, is equally well digested by horses and cattle, but the organic matter of feedingstuffs of high fibre content is less well digested by horses. The same is true of nitrogen-free extract. Protein is about equally digested by horses and cattle. Digestibility coefficients for crude fat and fibre are almost always less when a feed is used for horses than when it is used for cattle.

With rising fibre content in a ration, digestibility of organic matter is less for both horses and cattle, but the reduction is greater for horses. The relation between fibre content (x) and coefficient of digestibility of organic matter (y) is shown in the following equations, derived from a summary of 71 feeding experiments on horses with mixed rations and from an analysis of Kellner's digestibility experiments with cattle (Axelsson, 1940a; 1941):

For horses $y = 97.0 - 1.26 x$,For cattle $y = 86.0 - 0.66 x$.

N.A. and R., January 1955

TABLE 3

COMPARISON OF DIGESTION IN HORSES AND CATTLE

Feed	Animal	Digestibility coefficient				
		Organic matter	Crude protein	Ether extract	N-free extract	Fibre
Meadow hay, early . . .	Horse	58	63	22	65	48
(22 per cent. fibre) . . .	Cattle	67	65	57	68	63
Wheat straw	Horse	21	28	—	28	18
(41 per cent. fibre) . . .	Cattle	42	4	31	37	50
Oats	Horse	69	80	71	75	29
(10 per cent. fibre) . . .	Cattle	70	76	80	76	28
Maize	Horse	89	76	61	92	40
(2 per cent. fibre) . . .	Cattle	90	72	89	95	58

The digestibility of organic matter has been studied also with feeds differing in fibre content by Olsson (Larsson *et al.* (1951). The results are shown in Table 4.

TABLE 4

DIGESTIBILITY COEFFICIENTS OF ORGANIC MATTER IN HORSES AND CATTLE

Feed	Approximate fibre content per cent.	Horse	Cattle
Wheat straw	39	35	40
Clover-grass hay	30	50	63
Meadow hay	30	52	59
Pasture	18	64	81
Oats	10	78	72
Fodder cellulose	68	81	80

The discrepancy is smallest for fodder cellulose; but Hvidsten (1945b) records even higher values for ruminants and Edin, Helleday and Nordfeldt (1941) give values of from 63 to 92 per cent. for horses, depending on the nature of the product tested. From the results of roughly 1000 digestion experiments Olsson (1949) has fitted an equation of the third degree to express the relation of digestibility of dry matter to fibre content (see p. 12).

NUTRITIONAL REQUIREMENTS OF HORSES

Requirements for maintenance, work, reproduction and lactation, and growth must be considered separately, and with reference to energy supply and the essential components of food, namely,

protein, minerals and vitamins. Knowledge of metabolism, and especially metabolism of the individual components of feed, is incomplete and in some respects negligible.

A number of rationing systems have been used. Those best known are based on starch equivalent (S.E.), the Scandinavian feed unit (Sc. F.U.), the feed unit for ruminants (F.U.r.) based on metabolisable energy according to Axelsson, the Russian oat feed unit, and total digestible nutrients (T.D.N.). Computations in terms of the Scandinavian unit are based on the net energy value of the feed; the unit is the value of 1 kg. average barley. Olsson (1951) claims that this unit gives a reliable measure of the net energy requirements of the horse.

Requirements for Maintenance

Energy

The energy requirement of the horse for maintenance has been computed by several workers. The mean results are shown in Table 5.

According to some writers (Ehrenberg, 1932; Hansson, 1938) there is a direct relation between the horse's energy requirement for maintenance and its liveweight; others have found a somewhat lower requirement of energy per unit of weight as liveweight rises (Axelsson, 1943; Crasemann, 1945; Jespersen, 1949; Larsson *et al.*, 1951). In these calculations it is assumed that the requirement is proportional to the 5/8 power of liveweight (Axelsson, 1943; Larsson *et al.*, 1951). It has been confirmed in investigations in the United States (Procter, Brody, Jones and Chittenden, 1934) and elsewhere that maintenance energy requirement per unit liveweight decreases as weight increases.

THE NUTRITION OF THE HORSE

TABLE 5

DAILY ENERGY REQUIREMENT FOR MAINTENANCE

Authority	Unit of measurement	Liveweight: kg.					
		300	400	500	600	700	800
Kellner and Fingerling (1924)	Starch equivalent (kg.)	2.35	2.8	3.3	3.7	4.1	—
Hansson (1938)	Scandinavian feed unit	2.7	3.6	4.5	5.4	6.3	7.2
Jespersen (1949) ¹	" " "	2.9	3.6	4.3	5.0	5.7	6.3
Crasemann (1945) ²	Starch equivalent (kg.)	2.1	2.6	3.0	3.4	3.75	4.1
Ehrenberg (1932) ³	" " "	—	—	—	3.0	3.5	4.0
Axelsson (1943)	Feed unit for ruminants	4.0	4.8	5.5	6.2	6.8	7.4
Popov (1946)	Russian oat feed unit	4.2	4.8	5.5	6.2	—	—
Morrison (1937)	Total digestible nutrients	—	—	3.8	4.3	4.9	5.5
Larsson <i>et al.</i> (1951)*	Scandinavian feed unit	—	3.9	4.5	5.0	5.5	6.0

¹ Computed from the formula: requirement in Sc. F.U. = $0.03 W^{4/5}$, where W is the liveweight in kg.² Computed from the formula: requirement in kg. cal. metabolisable energy = $179.06 W^{3/2}$, where W is liveweight in kg.; 1 kg. S.E. = 3780 kg. cal. metabolisable energy.³ In the computation it is assumed that the energy requirement for maintenance of heavier horses is 5.0 kg. S.E. per 1000 kg. liveweight.

* Norms recommended by the authors.

Table 6 compares the standards in Table 5, all in Sc. F.U. The comparison is based on the assumption that the fodder used is grass hay harvested before flowering.

TABLE 6

ENERGY REQUIREMENT FOR MAINTENANCE IN SCANDINAVIAN FEED UNITS

Authority	Liveweight: kg.					
	300	400	500	600	700	800
Kellner and Fingerling (1924)	3.2	3.9	4.5	5.1	6.0	—
Hansson (1938)	2.7	3.6	4.5	5.4	6.3	7.2
Jespersen (1949)	2.9	3.6	4.3	5.0	5.7	6.3
Crasemann (1945)	2.9	3.5	4.1	4.6	5.1	5.6
Ehrenberg (1932)	—	—	—	4.1	4.7	5.4
Axelsson (1943)	3.0	3.6	4.1	4.6	5.1	5.5
Popov (1946)	3.5	4.0	4.6	5.2	—	—
Morrison (1937)	—	—	3.5	4.0	4.5	5.1
Larsson <i>et al.</i> (1951)*	—	3.9	4.5	5.0	5.5	6.0

* Norms recommended by the authors.

The highest estimate is that of Popov. Kellner and Fingerling's estimates for light horses and Hansson's for heavy are high. Morrison's standard is relatively low.

Protein

Table 7 shows estimates by different writers for average protein requirements for maintenance.

TABLE 7

PROTEIN REQUIREMENT FOR MAINTENANCE PER 100 KG. LIVELWEIGHT

Authority	Digestible protein g.	Digestible true protein g.
Hansson (1938)	—	65-70
Jespersen (1949)	—	about 52
Crasemann ¹ (1945)	—	02-80
Nitsche (1939)	53-68	48-50
Ehrenberg (1932) (heavy horses)	—	60
Popov (1946)	—	55-65
Morrison (1937)	60-80	—
Axelsson (1943)	about 77-100	—
Larsson <i>et al.</i> (1951)*	—	55-70

¹ Computed from the formula: digestible true protein requirement in g. = $5.8 W^{3/2}$ for horses of 400 to 800 kg. liveweight, where W = liveweight in kg.

* Norm recommended by the authors.

According to most writers, protein requirement is directly proportional to the animal's liveweight. Crasemann (1945), on the other hand, computes that the horse's requirement of true protein for maintenance rises as the $2/3$ power of liveweight, but does not regard the point as sufficiently well established. Most authors give the horse's requirement of protein for maintenance in terms of digestible true protein and the standards vary between 48 and 80 g. per 100 kg. liveweight. Axelsson (1943) and Morrison (1937) express the requirement

N.A. and R., January 1955

in terms of digestible protein. Axelsson's standard is higher than Morrison's. The expression of the requirement as digestible protein involves the assumption that amides are at least partly utilised.

Requirements for Work

Energy

The energy requirement of working horses depends on several modifying circumstances, namely, the kind of work, the incline of the ground to be worked, the speed of work, the liveweight of the horse, its training and its individuality. In addition, energy requirement may be affected by handling, including harnessing, the care of the hooves and the degree of tiredness, and by climate and weather. Zuntz and Hagemann (1898) studied energy expenditure of horses at work with reference to modifying circumstances. But it is impossible in practice to take account of all such circumstances, especially in such variable work as agriculture. Therefore, energy requirement has been computed for a few classes of work.

Kellner and Fingerling (1924) allocated work to three grades, assuming a horse of 500 kg. weight, and including the cost of moving the body :

Light work :	in a day about	700,000 kg.-metres
Medium (normal) work :	" "	1,300,000 "
Heavy work :	" "	2,250,000 "

Other authors (Crasemann, 1945 ; Hansson, 1938 ; Høie and Tilrem, 1951) have introduced a fourth grade, very heavy work. Wrede (1932) suggests the following grades of performance for a working horse weighing 500 kg. :

Grade	Mean daily work, including movement of the body: million kg.-m.	mean
Light work	0.0-1.0	0.5
Normal work	1.0-2.0	" 1.5
Heavy work	2.0-3.0	" 2.5
Very heavy work:	over 3.0	

Ehrenberg (1932) and Jespersen (1949) divide work performance of horses into five grades : very light, light, medium, heavy and very heavy work.

The energy requirement given by different workers for the standard 500-kg. horse is shown in Table 8, in which 3 or 4 grades of work are assumed.

The standards given in Table 8, re-computed to Scandinavian feed units on the assumption that the horse is fed on oats of normal composition, are shown in Table 9.

It appears from Table 9 that Kellner and Fingerling's standard is highest and Morrison's lowest.

Vol. 25, No. 1

TABLE 8

ENERGY REQUIREMENT ABOVE MAINTENANCE FOR WORK,
COMPUTED FOR A HORSE OF 500 KG. LIVELWEIGHT

Authority	Unit	Grade of Work			
		Light	Normal	Heavy	Very heavy
Kellner and Fingerling (1924)	S.E. kg.	1.5	2.4	4.2	—
Hansson (1938)	Sc. F.U.	2.0	3.3	4.8	Over 5.5
Crasemann (1945)	S.E. kg.	1.3	2.0	3.25	4.15
Axelsson (1943)	F.U.r.	1.7	3.4	5.1	—
Popov (1946)	Russian (oat) F.U.	1.9	3.6	6.0	—
Morrison (1937)	T.D.N. kg.	0.9	4.4	7.3	—
Larsson <i>et al.</i> (1951) *	Sc. F.U.	1.6	3.2	4.9	—

* Norms recommended by the authors.

TABLE 9

ENERGY REQUIREMENT FOR WORK IN SC. F.U.
COMPUTED FOR A HORSE OF 500 KG. LIVELWEIGHT

Authority	Grade of work			
	Light	Normal	Heavy	Very heavy
Kellner and Fingerling (1924)	2.2	3.6	6.3	—
Hansson (1938)	2.0	3.3	4.8	Over 5.5
Crasemann (1945)	1.9	3.0	4.8	6.1
Axelsson (1943)	1.7	3.4	5.1	—
Popov (1946)	1.7	3.3	5.5	—
Morrison (1937)	1.3	2.6	4.3	—
Larsson <i>et al.</i> (1951) *	1.6	3.2	4.9	—

* Norms recommended by the authors.

Jespersen (1941a) has given the following energy standards for work, by grade and per hour of work :

Grade	Addition per hour of work Sc. F.U.
Very light	0.2
Light	0.3
Medium	0.5
Heavy	0.7
Very heavy	1.0

Protein

According to Nitsche (1939) the true protein requirement of the horse, computed per unit of work

(0.1 million kg.-m.), falls as work output increases. He gives the following allowances:

Million kg.-m. of work	Digestible true protein, g. per 0.1 million kg.-m.
0.5-0.6	80
0.6-0.7	81
0.7-0.8	67
0.8-0.9	65
0.9-1.0	59
1.0-1.1	53
1.1-1.2	—
1.2-1.3	50

Meyer (1944), on the other hand, holds that increase in intensity of work has no effect on protein requirement. Morrison (1937) says that the older protein standards are too high. On the other hand, he believes (p. 68) that if the protein allowance is too low, the digestibilities of other nutrients may be reduced (see also p. 12). He suggests that the micro-organisms in the digestive tract which normally break down cellulose will attack sugars or starch if the ration is rich in these more readily available carbohydrates. The best ratio of nitrogen-containing to nitrogen-free nutrients for working horses is thought to be 1:9-11 and for non-working horses 1:10-12. Axelsson (1943) takes for work the same protein requirement as for maintenance, namely, 75 to 83 g. per F.U.R. Hansson (1938) considered 65 to 70 g. digestible true protein per Sc.F.U. sufficient for working horses.

For different grades of work, Ehrenberg (1932) proposes the following supplements of digestible true protein per 1000 kg. liveweight daily:

Grade of work	Digestible true protein g. daily
Very light	200
Light	300
Medium	600
Heavy	900
Very heavy	1250

Jespersen (1949) gives the true protein requirement of working horses as 60 g. per Sc.F.U. with variations between 56 and 60 g. on the assumption that the energy allowed is not greater than is needed for the work. Larsson *et al.* (1951) assess the working horse's requirement of digestible true protein as 70 to 75 g. per Sc.F.U.

Table 10 gives the mean protein standards recommended by different authors for 3 or 4 grades of work. It is evident that agreement is not complete on the requirements for work. For work alone Popov's are highest and Morrison's lowest.

Objections have been made to the energy and protein standards of Kellner and of Hansson on the basis of German experiments under Ehrenberg's

TABLE 10.

PROTEIN REQUIREMENT IN G. FOR DIFFERENT GRADES OF WORK, COMPUTED FOR A HORSE OF 500 KG. LIVWEIGHT

Authority	Grade of work			
	Light	Normal	Heavy	Very heavy
Kellner and Fingering (1924) ^{1, 2}	500	700	1000	—
Hansson (1938) ¹	145	220	320	Over 370
Axelsson (1943) ^{3, 4}	134	260	403	—
Popov (1946) ^{1, 4}	180	335	500	—
Morrison (1937) ^{3, 4}	113	204	295	—
Larsson <i>et al.</i> (1951) ^{1, *}	115	235	355	—

* Norms recommended by the authors.

guidance. In most of the objections it is argued that both standards are too high (Asam, 1924; Bartsch, 1926; Klose, 1929; Temper, 1927; Teschner, 1927; Wrede, 1932). One of these (Klose, 1929) maintains that Hansson's protein standards are too low.

Requirements for Reproduction

Most statements on requirements for reproduction are based on practical experience and judgment, not on the results of exact experiment.

Pregnant Mares

Energy. During the first half of pregnancy no increase in energy allowance above normal is considered necessary. Additional feed for growth of the foetus is not considered necessary until the seventh month.

Some authors (Axelsson, 1943; Popov, 1946) believe that the energy requirement for foetal growth is related to the liveweight of the mare. Others (Larsson *et al.*, 1951) think that no distinction should be made between mares of different weights and that their requirements for growth of the foetus are almost equal (see Table II). Popov (1946) states the energy requirement for the foetus in terms of the weight increase of the mare in the last months of pregnancy. According to him, the mare puts on 10 to 12 per cent. of weight during pregnancy. He considers that per kg. liveweight the mare needs 4 to 4.5 Russian (oat) feed units (3.2 to 3.6 Sc.F.U.). On that basis the requirements

N.A. and R., January 1955

TABLE 11

ENERGY REQUIREMENT FOR GROWTH OF THE FETUS

Month of pregnancy	Liveweight of the mare: kg.						Larsson <i>et al.</i> (1951)*
	500		600		700		
	Additional feed in Sc.F.U. daily according to

¹ On the assumption that the additional feed consists of the usual concentrates, 1 F.U. = 1 Sc.F.U.² Computed, 1 Russian (cat) F.U. taken as 0.8 Sc. F.U.

* Norms recommended by the authors.

for the foetus according to Popov are twice those proposed by Axelsson and by Larsson *et al.* (1951) (see Table 11). Jespersen (1949) thinks the energy allowance of the pregnant mare should be increased by $\frac{1}{2}$ to 2 Sc.F.U. daily after 6 months. Dobrynin (1950) found that the plane of nutrition affected the duration of pregnancy. With correct feeding it was on the average 333 days, and with restricted diet 352 days.

Protein. As pregnancy advances the protein requirement of the mare increases. Axelsson (1943) considers that the supplementary feed given to the pregnant mare should have 160 g. digestible protein per F.U. Jespersen (1949) recommends 80 to 100 g. digestible true protein per Sc.F.U. of total feed. Popov (1946) suggests 90 to 100 g. digestible true protein per Russian (oat) feed unit as a suitable proportion in the total feed. That corresponds to 112 to 125 g. digestible true protein per Sc.F.U. Olsson (Larsson *et al.*, 1951) recommends from the seventh month of pregnancy 80 to 85 g. digestible true protein per Sc.F.U. of total feed.

The protein content of the ration may affect the mare's fertility. Jespersen (1949) asserts that the mare is less likely to become pregnant if she is given a low-protein diet. He recommends at least 80 g. digestible true protein per Sc.F.U. for the non-pregnant mare.

Lactating Mares

Energy and protein. The requirements of the mare during lactation depend on the milk yield and the composition of the milk. On the assump-

tion that mare's milk contains on the average, per cent., protein 1.98, fat 1.03 and sugar 6.19, and that the energy value of the fat is 9.11, of the protein 5.86 and of the sugar 3.95 Cal. per g., the energy value of mare's milk is about 450 Cal. per kg. (Cow's milk with 4 per cent. fat has an energy value of about 750 Cal. per kg.) That implies that the requirement of energy for production of milk of the above composition is 0.25 Sc.F.U. per kg., if the mare's efficiency is comparable with that of the dairy cow. The protein requirement for milk production may, in the same way, be about 37 g. digestible true protein per kg. milk.

Milk production daily litres	Requirements per 1000 kg. liveweight		
	Digestible true protein kg.	Starch equivalent kg.	Sc.F.U. ¹
1. With light work			
5	1.0	7.5	10.7
10	1.2	8.5	12.2
15	1.4	9.5	13.5
20	1.6	10.5	15.0
25	1.8	11.5	16.4
2. With moderate work			
5	1.4	9.2	13.2
10	1.6	10.2	14.6
15	1.8	11.2	16.0
20	2.0	12.2	17.4
25	2.2	13.2	18.9

¹ Conversion: 1 kg. S.E. = 1.43 Sc. F.U.

According to Axelsson (1943) 0.28 F.U.r. and 45 g. digestible protein are required to produce 1 kg. mare's milk. Popov (1946) computes the energy requirement to be 0.33 Russian feed unit (about 0.26 Sc.F.U.) with 30 to 35 g. digestible true protein per kg. milk. Ehrenberg (1932) and Provovnik (1931) consider that 200 g. starch equivalent (about 0.28 Sc.F.U.) and 40 g. digestible true protein are required to produce 1 kg. mare's milk. Provovnik recommends for the lactating mare doing moderate work about 16.5 kg. S.E., 2.9 kg. digestible true protein and 35 kg. dry matter daily, per 1000 kg. liveweight. On the basis of his own experiments, Ehrenberg (1932) proposed the following standards for the breeding mare, assuming that 200 g. S.E. and 40 g. digestible true protein are required per kg. milk.

Stallions

Energy and protein. The services required of the stud stallion may vary widely and that affects requirements. Axelsson (1943) considers that stud stallions, in addition to the energy for maintenance and work, should have 0.5 to 1.0 F.U.r. daily. During the breeding season, and depending on the demands made, he recommends the following additional allowances:

Light breeding:	0.5 to 1.5 F.U.r.	per head	daily
Moderate "	1.5 to 2.5 "	" "	" "
Heavy "	2.5 to 3.5 "	" "	" "

The total feed should provide 100 to 125 g. digestible protein per F.U.r. and the supplementary feed 200 to 230 g. per F.U.r. According to

Jespersen (1949) a stallion that serves 70 to 100 times in 4 or 5 months requires about as much energy as when working. The protein requirement for a breeding stallion serving once daily he estimates at 700 to 800 g., and for a stallion serving 3 or 4 times daily 1000 g. Popov (1946) recommends 0.95 to 1.2 kg. digestible true protein and 9.5 to 10 Russian F.U. (7.6 to 8.0 Sc.F.U.) daily for stallions of light breeds, with a liveweight of 450 to 500 kg., and regards these amounts as adequate even for intensive breeding for 3 to 5 months. Ehrenberg (1932) proposes for breeding stallions an increase of the daily allowance by 200 g. digestible true protein per 1000 kg. liveweight but only a small increase in energy supply. Olsson (Larsson *et al.*, 1951) estimates for breeding stallions with moderate intensity of breeding an increase of 0.5 to 1.0 Sc.F.U. daily, with 100 to 200 g. digestible true protein per Sc.F.U.

Requirements for Growth

Hansson and Müller (1929) made feeding experiments during the years 1923-28, and recorded rate of growth and feed consumption of foals of light breed. Olsson (1952) has published the results of a study in 1945-50 of the rearing of Ardenne horses. The results of their experiments provide a good guide for the computation of feeding standards for foals of these breeds under Swedish conditions.

Energy. Table 12 gives data for energy requirements of foals according to four different authors. To give comparable values, Axelsson's and

TABLE 12

TABLE 13

ENERGY REQUIREMENT OF FOAL ACCORDING TO AXELSSON IN F.U.F. AND MORRISON IN T.D.N.

Liveweight kg.	Axelsson (1943)		Morrison (1937) kg.
	Liveweight at 3 years: 600 kg.	Liveweight at 3 years: 800 kg.	
250-300	6.90	8.45	3.84
300-350	7.10	8.60	4.33
350-400	7.30	8.75	4.82
400-450	7.45	8.90	5.38
450-500	7.55	9.05	5.78
500-550	7.60	9.15	6.18
550-600	7.55	9.25	
600-650		9.35	
650-700		9.45	
700-750		9.50	
750-800		9.45	

Morrison's standards have been converted to Sc.F.U. The original data are shown in Table 13.

From the data in Table 12 it appears that Axelsson's standards for foals of both light and heavy breeds exceed those of other writers. Hansson's allowances are also above those recommended by Olsson for light breeds. Morrison's standards are less for young foals, up to 300 kg. liveweight, than those proposed by Olsson for foals of light breeds.

According to Jespersen (1949), the energy requirement of the foal in its first winter is, on the average, 5 to 5.5 Sc.F.U., and in its second winter 6 to 6.5 Sc.F.U. daily. Broadly, these allowances correspond with those proposed by Olsson. Popov (1946) recommends the following daily allowances for foals:

Liveweight (kg.)	200	250	300	350	400
Sc.F.U. ¹	4.0	4.6	5.0	5.4	5.8
Digestible true protein (g.)	500	570	630	600	580

¹ 1 Russian (oat) F.U. = 0.8 Sc.F.U.

According to Olsson (1952), foals of the Ardennes breed require the following allowances of energy in Sc.F.U. per kg. weight gained:

Age in months	Mean weight increase (kg.)	Per kg. weight gain (Sc.F.U.)
0-6	229	4.34
7-12	149	7.75
13-18	100	12.10
19-24	79	15.63
25-30	77	21.71
31-36	27	52.30

Vol. 25, No. 1

From this it appears that the foal's feed consumption per kg. weight gain increases rapidly with age. During the last six months, the 31st to the 36th, it puts on 27 kg., equivalent to about 12 per cent. of the weight gained in the first six months. The continuous increase in feed consumption per kg. weight gained depends chiefly on the rise in maintenance requirement as weight increases.

Protein. The protein requirement of the foal, according to four authors, is shown in Table 14. It will be seen that Morrison's proposed standards are relatively low, Axelsson's relatively high; Hansson's are higher than Olsson's. Axelsson's allowances fall continuously as weight increases and Hansson's and Morrison's rise. According to Olsson, protein requirement is at a maximum at 425 and 575 kg. liveweight, less at the beginning and end of growth. Popov (1946) adopts the same pattern, but holds that protein allowances may be reduced when 300 kg. liveweight has been attained. Derevlev (1946), according to the rate of growth, computes the following allowance for foals 6 to 12 months old:

	Requirements for different rates of weight increase, g. daily		
	1 kg.	0.8 kg.	0.5 kg.
Digestible protein	950-1000	850-900	750-800
Fat	350-370	300-320	250-270
Sugar	350-400	350-400	350-400
Ca.	65-67	60-65	55-60
P.	32-35	30-33	25-30

Minerals

Horses as a rule require more sodium chloride and more of some other inorganic salts than are present in feed.

Salt (sodium chloride). Requirements for Na and Cl depend to some extent on the work done, the temperature and humidity of the air and other circumstances. The need to add salt depends also on how much is already present in the feed. According to experiments in Russia (Popov, 1946) excretion of NaCl by horses increases with the intensity of work. During a pull of 50 km., 50 to 60 g. NaCl was excreted in sweat and 35 g. in the urine, or 85 to 95 g. daily. The diet of 5 kg. hay and 5 kg. oats provided only 30 to 35 g. NaCl and part of that was lost in the faeces. Consequently the salt balance was negative. Kellner and Fingerling (1924) recommend 15 to 25 g. salt daily for grown horses, to be mixed with the feed. They regard salt blocks as unsuitable, since horses take too much. According to Liebscher (1934), sudden death as the result of heavy work with excessive

THE NUTRITION OF THE HORSE

* Norms recommended by the authors.

sweating is due to loss of chloride. Such a catastrophe may be avoided if the horse has free access to a salt block or is given 30 to 70 g. salt after work. Ehrenberg (1932) suggests 40 g. salt per 1000 kg. liveweight as a suitable allowance, and adds that an extra supplement of salt should be given when molasses is used in the feed. He too does not approve of salt blocks. Dobrynin, Davydova and Skachkov (1949) give the following daily salt allowance for horses:

	Young horses g.	Grown horses g.
Stud horses of light breeds	15 to 30	30 to 50
Stud horses of heavy breeds and working horses	20 to 40	40 to 70

According to Jespersen (1949) horses need 10 to 15 g. salt daily. Olsson (Larsson *et al.*, 1951) recommends the following daily allowances of salt, in g.:

Young horses	15 to 40
Working horses	20 to 40
Pregnant mares	25 to 45
Lactating mares	30 to 45
Stallions in the breeding season	30 to 45

These standards correspond in general with Axelsson's (1943).

Iodine. There is usually enough iodine in a horse's feed to meet its requirements, but in areas where the iodine supply is low, goitre may develop if the horse is not given a supplement with its feed. It is specially important that the needs of pregnant and lactating mares should be satisfied.

Where there is deficiency of iodine, iodised salt should be used for horses. It usually contains 5 mg. potassium iodide per kg.

Calcium and phosphorus. Svanberg and Johansson (1936) maintain that deficiency of Ca or P or both, if large enough, will cause disorders of bone, even in fully grown horses. Where there is plenty of lime, horses are relatively less sensitive than ruminants to lack of phosphorus, but these authors believe that horses' rations are often deficient in phosphorus.

On the basis of experiments by Scheunert, Schattke and Wiese (1923) and Bang (1925), Breirem (1938) computed that daily rations of 12 to 15 g. Ca and 12 to 15 g. P are sufficient for full-grown horses of 500 kg. liveweight. He maintains that the Ca : P ratio should not be less than 0.7. Axelsson (1943), on the other hand, suggests 30 to 40 g. Ca daily for full-grown horses. He considers that the Ca : P ratio for working horses may be less than that recommended for young horses, 1.5 to 1.7.

According to Harvey, Thomas, Culbertson and Collins (1943), the horse's requirement of Ca and P is not affected by the intensity of work. Balance experiments with two Percheron geldings weighing about 760 kg. gave the following results with average daily intakes of Ca and P between 18 and 19 g. per horse:

	Excreted daily: g.		
	Light work	Medium work	Heavy work
Ca	22 to 36	27 to 37	25 to 32
P	25 to 34	27 to 38	26 to 45

N.A. and R., January 1955

Mitchell and McClure (1939) gave the following Ca and P allowances daily for growing horses :

	Ca in g.	P in g.
For maintenance	4.5	8.9
For growth	9.0	4.7
Together	13.5	13.6

The Ca : P ratio should be about 1.

Dobrynin *et al.* (1949) recommend, when only small amounts of hay are allowed, or the hay is of poor quality, the following daily allowances of Ca :

	Young horses g.	Grown horses g.
Stud horses of light breed	20 to 30	30 to 60
Stud horses of heavy breed and working horses	30 to 50	50 to 100

Ehrenberg (1932) considers that horses given feeds rich in sugar, or potato pulp and similar feeds, should be given daily 100 g. ground chalk per 1000 kg. liveweight. According to Jespersen (1949) a working horse of 600 to 700 kg. weight needs about 20 g. Ca and 20 g. P daily. Mares in late pregnancy, or lactating, should have 1.5 to 3 times as much.

Schecker (1943) thinks that mineral deficiency causes loss of appetite, slow pulse and fall of body temperature.

Axelsson (1943) and Olsson (Larsson *et al.*, 1951) give the following Ca and P allowances :

	g. per head daily	
	Ca	P
Full grown horses on maintenance ration	20-30	14-20
Growing foal : 6 months old	30-40	18-24
12 "	33-45	21-28
24-28 "	30-40	20-27
Working horse	30-40	21-29
Stud mare : late pregnancy	50-70	31-44
lactating	60-75	40-50
Stud stallion	60-75	40-50

Vitamins

Fat-soluble vitamins. Little is known of the vitamin needs of horses, but there are some statements in the literature. For rachitic foals Morrison (1937) recommends about 30 g. fish liver oil daily or an equivalent amount of some other source of vitamin D. Klemola (1933) showed that army horses that had been fed for a long time on hay, oat straw and oat grain without fresh green forage had deformed hooves. The horny layer was unevenly laid down and the horn was brittle. Extra rations of fresh grass, A.I.V. silage or cod liver oil prevented the abnormality, which was regarded as due to deficiency of vitamin A. Scheunert and Schieblich (1934) and Howell, Hart and Ittner (1941) also have shown that horses are sensitive to lack of vitamin A or carotene.

Edwards (1937-38) discusses disorders in horses caused by deficiency of vitamin A. He assesses the requirement of carotene at about 30 μ g. per kg. liveweight daily.

Gulbert, Howell and Hart (1940) fed horses on fodder of low vitamin A content and from the results estimated the requirement of carotene or vitamin A. The first sign of deficiency was night blindness. If vitamin A was not given then, the signs increased gradually for 3 or 4 months. The coat became rough, the cornea became opaque and daylight vision also was impaired. Instead of xerophthalmia, there was lachrymation. The animal was restless and resentful of handling. Within a month of treatment with vitamin A most of the signs had disappeared. The horse's requirement of vitamin A is estimated at 4.2 to 5.3 μ g. per kg. liveweight daily or 20 to 30 μ g. carotene, for instance, in dried alfalfa. These quantities correspond to 14 to 18 I.U. vitamin A (alcohol) or 33 to 50 I.U. carotene and are considered sufficient for growth and to prevent deficiency, but not enough to give any storage in the body. Further, 3 or 4 times as much was thought to be necessary for reproduction and lactation.

Crasemann (1945), on the basis of the requirements of other domestic animals, computes the requirement of a 500-kg. horse as 10.0 to 12.5 mg. carotene daily. In the same way, he computes the vitamin D requirement as 0.04 to 0.08 mg. daily.

According to Popov (1946), deficiency of vitamins A and D causes low fertility in mares and abortion or premature birth of weakly foals. Young mares are believed to be more sensitive than older ones to deficiency of vitamins.

The studies of Galichnikova and Kulikova (1951) showed that deficiency of vitamin A produced keratinisation of the mucosa of the digestive canal and so reduced glandular secretions. In addition the hydrochloric acid of gastric juice was abnormally low, so that digestion could not proceed normally.

Sokolov and Sekulov (1951) found that a supplement of 50 mg. carotene dissolved in 100 ml. oil improved the digestibility of a carotene-free ration and the balances of N, Na, Ca and P.

Olsson (Larsson *et al.*, 1951) gives the following allowances for vitamin A :

	Per 100 kg. liveweight daily Vitamin A : I.U. Carotene: mg.
Foals and young horses	5000 to 7500 or 12 to 15
Working horses	10 to 12
Pregnant mares and stud stallions	15 to 20
Lactating mares	100 to 150

Rjabov (1946) gave vitamin E experimentally as wheat germ, 0.5 kg. per head daily for 3 or 4 days.

The result was oestrus in barren mares and better quality of semen in stallions.

Water-soluble vitamins. It is not certain to what extent micro-organisms in the intestine of the horse can synthesise B vitamins as they do in cattle and other ruminants. That deficiency disease could not be demonstrated in horses fed on forage of low vitamin B content under certain circumstances suggests that intestinal synthesis is possible. Under other circumstances deficiency of vitamin B₁ has been demonstrated, but that does not prove that there is no possibility of intestinal synthesis in the horse.

Carlström and Hjärre (1939) have shown that deficiency of vitamin B₁ can occur in horses fed on grain and hay, both of poor quality. The deficiency was characterised by emaciation in spite of good appetite; the coat became dull and there was anaemia and disturbance of heart action. The emaciation was thought to arise from faulty carbohydrate breakdown, resulting from vitamin B₁ deficiency. Health was restored when a supplement of 250 g. dried yeast was given daily.

Reports of bracken (*Pteris aquilina*) poisoning in the horse responding to injections of vitamin B₁ have appeared (Roberts *et al.* 1949; Carpenter *et al.* 1950).

Westerlund (1938; 1941) insists that it is important that horses have plenty of vitamin B₁ and nicotinic acid. Kjos-Hansen (1944) found that a foal that had convulsions recovered after a week's intravenous injection of vitamin B₁ and simultaneous administration by mouth of "vitamin B". According to Olsson (Larsson *et al.*, 1951), vitamin B₁ deficiency in horses will not occur if 40 to 50 g. dried yeast is given daily in their feed. Pearson, Sheybani and Schmidt (1944) have found that the riboflavin requirement of horses is met by 44 µg. per kg. liveweight daily. Horses synthesise nicotinic acid in the body and special supplies of that vitamin are not needed (Pearson and Luecke, 1945).

DIGESTIBILITY OF FEED

The number of digestion experiments made on horses is much less than on ruminants, and still too low to afford a firm basis for the evaluation of feedingstuffs for horses. They provide information on the digestibility of some single feedingstuffs. Table 15 shows the averages for chemical composition and coefficients of digestibility of nutrients in 577 published digestion experiments with horses in which single feeds were studied.

Circumstances which Affect Digestion in the Horse

Individuality. The individuality of the horse to some extent determines the digestibility of feed.

Edin and Eriksson (1929) and Olsson (1943) found that individual differences in digestion of a particular feed were large. In addition, several outside influences affect digestion.

Chemical Composition of Feed. It is known that the digestion of feed depends partly on its chemical composition. At the National Animal Experiment Station, the results of 1094 published digestion experiments have been summarised (Olsson, 1949). From these it appears that the relation of the digestibility coefficient for organic matter (*y*) to percentage of fibre in dry matter (*x*) of the feeding-stuff may be expressed by a curve with the equation

$$y = 99.71 - 3.066x + 0.0679x^2 - 0.00056x^3.$$

With increase of fibre in dry matter the digestibility of other nutrients is reduced. In the feeds represented, fibre content ranged from 2 to 48 per cent. of dry matter. No account was taken of differences in chemical composition of fibre.

From this collection of experimental data it appeared also that digestibility coefficients for protein rose with increase of protein in the feed to about 20 per cent. and then fell (*cf.* p. 14). With rising protein content, the digestibility coefficient of N-free extract rose and that for ether extract fell. As the percentage of crude fat in dry matter rose, the digestibility coefficient rose also, as did the coefficients for protein and N-free extract.

Digestibility of organic matter, like that of the several nutrients, depends not only on the gross fibre content of the feed, but in large degree on the composition of the fibre, as was shown by Nordfeldt (1954) in experiments on pigs. It is not known to what extent this is true for horses, but there is much evidence in favour of it.

Axelsson (1943) recommends the following limits to fibre in dry matter for growing horses of different ages, breeding stock and working horses:

Fibre in dry matter: per cent.		
Young horses	6-12 months	20-23
	12-18 "	22-25
	18-24 "	24-27
	24-30 "	25-29
	30-36 "	25-30
Breeding stock		
Mares in late pregnancy (light work)		25-28
Lactating mares (light work)		18-21
Stud stallions		18-22
Working horses		
Maintenance		27-31
Light work		26-29
Normal work		22-25
Heavy work		18-21

N.A. and L., January 1955

Feed Capacity. The digestion of feed depends partly on the amount of feed given. In experiments on heavy work horses Hansson (1924) found that hay was better digested when only 6 to 8 kg. per head was given daily. Edin and Eriksson (1929) showed that the amount of feed dry matter has no definite effect on digestion until it exceeds 2 kg. per 100 kg. liveweight daily.

Rate of Working. From experiments made it appears that digestion may be affected in horses by work or exercise in such a way that it is improved by light exercise and may be inhibited by heavy work. That is true for instance of the studies of Grandeau and Le Clerc (1884). With digestibility at rest as 100, relative values for different amounts of work were:

Rest	100
Walking without load	106
Walking with load	101
Trotting without load	98
Trotting with load	97

Kellner (1880), on the other hand, could find no difference in the digestion of organic matter by horses doing light and heavy work; but Edin and Eriksson (1929) found that the digestibility of organic matter was less when horses moved very quickly.

Grinding, Water Content and Time of Transit through the Digestive Tract. Grinding feed (crushing or milling) under certain circumstances improves digestion. Morrison (1937) considers that the nutritive value of oats for horses, young and old, is improved by milling. The chopping of roughage seems to have no effect on digestibility (Axelsson, 1940b) or on nutritive value (Hofman-Bang, 1910). According to Ehrenberg (1932) and Jespersen (1949), fodder should not be chopped shorter than 3 cm. or it may cause disturbances of digestion.

The water content of feed may affect digestion. Taubert (1934) showed that horses digest feed less well if the water content is high. Wittig (1938) found that much energy is lost in sweating if the intake of water is much in excess of what is normally eliminated in urine and faeces.

Time of transit through the digestive tract has been studied by Edin and Eriksson (1929) and at the National Animal Experiment Station (Olsson, Kihlén and Cagell, 1949). The latter study was made with meadow grass or hay and oat straw with crushed oats as supplement; chromic oxide was used as indicator. The results are shown in the following summary. (See next Column.)

From this it appears that freshly cut grass passes through the digestive tract of the horse more rapidly than hay of the same cut. The difference depends, probably, on the difference in water

content. Straw moves at approximately the same rate as hay. Hill (1952) confirmed the great variation in time of transit of feed by X-ray with a barium feed.

Bulk. This is determined chiefly by the amount of fodder in the ration and particularly by the fibre present. The more fibre there is in the dry matter of a ration, the greater the bulk.

Time Interval: day	Percentage marker recovered in faeces		
	Fresh grass and oats	Hay and oats	Straw and oats
0-1	16.8	6.5	10.6
1-2	76.1	66.7	72.0
2-3	6.4	24.0	15.2
3-4	0.4	2.45	1.7
4-5	0.3	0.3	0.45
5-6	0.1	0.1	0.1

IMPORTANCE OF DIFFERENT FEEDINGSTUFFS

The views of different writers about the importance and use of different feedingstuffs in rations for horses differ widely.

Coarse Fodder

Kellner and Fingerling (1924) give the daily allowance of roughage for horses doing light work as 10 to 15 kg. per 1000 kg. liveweight. Hansson (1938) recommends 7 to 8 kg. roughage (straw and hay) daily.

For horses doing an average amount of work Simms and Williams (1931) compared the following rations of hay: 3.6, 5.4 and 7.3 kg. per head daily, with 5 to 7 kg. oats or oats and ground maize. The weights of the horses were between 540 and 770 kg. From the results, 3.6 kg. hay, corresponding to 0.5 to 0.7 per cent. of the liveweight of the horses, appeared to be the minimum desirable amount per day.

Harvey (1935) investigated the reaction of horses to different amounts of roughage in the ration, and found that 0.2 kg. hay per 100 kg. liveweight was insufficient for horses doing moderate amounts of work, but that 0.6 kg. was suitable when the horses had, at the same time, 0.6 to 1.2 kg. oats per 100 kg. liveweight daily. More recently other writers (Bünger, 1944; Crasemann, 1945; Hvidsten, 1945a; Karlsen, 1946; Schirch, 1943) have experimented with varying and sometimes very large daily rations of roughage for working horses. The results are not sufficiently clear to indicate the best amount of roughage for horses. According to Earle, Ellis and Greer (1943), the minimum amount of roughage (hay) a horse should have daily is 0.4 kg. per 100 kg. liveweight.

TABLE 15
SUMMARY OF THE RESULTS OF DIGESTION TRIALS WITH HORSES

Feedingstuff	No. of experiments	Dry matter per cent.	Chemical composition of dry matter: per cent.						Coefficient of digestibility

 Maize : Lindsey *et al.* (1926) ; Müntz (1882) ; Patterson (1879) ; Winkler (1940) ; Wolff (1879, 1887).
 Legumes (beans, sweet lupins, peas) : Müntz (1882) ; Müntz and Girard (1883) ; Toepsh (1937) ; Wolff (1879, 1881).
 Wheat bran and wheat feed : Hagemann (1911a) ; Lindsey *et al.* (1926) ; Müntz (1882) ; Olsson *et al.* (1949).
 Oat bran, oat chaff and oat feed : Lahtorp and Bohstedt (1938) ; Lindsey *et al.* (1926).
 Barley feed : Hötzel and Müller (1933).
 Cottonseed cake meal : Lindsey *et al.* (1926).
 Linseed cake meal : Lindsey *et al.* (1926).
 Soya bean meal : Olsson *et al.* (1949).

On the basis of extensive studies on Ardennes working horses, Olsson (1951) found that when they were doing no work or light work they were not satisfied with 5 to 6 kg. roughage (hay and straw) ; but when they did moderate to heavy work and had more concentrates they were satisfied with that amount of roughage, which corresponds to 0.6 to 0.7 kg. per 100 kg. liveweight. Olsson recommends not less than 7 kg. for rest or light work.

Pasture and Green Fodder

According to Blechschmidt (1933) a 2-year-old horse of heavy breed in dry weather can eat 40 kg. pasture grass. Nietsch (1935) says that a year-old foal on the average will eat 21 to 38 kg. grass daily. But the amount eaten on free grazing may vary within wide limits, depending on air temperature and other climatic differences. According to Schmidt, Patov and Kleisch (1945), working horses will eat 80 to 110 kg. green fodder harvested at an early stage of growth, or 50 to 60 kg. at a later stage of development.

Silage

Morrison (1937) says that grass silage can with advantage replace a third or a half of the ration of hay. Popov (1946), on the basis of Russian experiments, states that 6 to 12 kg. is a suitable amount of grass silage for working horses, and 20 kg. of maize silage. Axelsson (1943) thinks that the amount of silage should be restricted to 5 to 6 kg. daily ; Jespersen (1949) recommends 10 to 15 kg. and Chaljuk (1946) 12 to 20 kg.

Potatoes and Roots

These may be of great importance for feeding horses. The amount will obviously depend on the total bulk and on the work to be done. Kellner and Fingerling (1924) recommend 1.5 to 2.5 kg. raw potatoes per head daily for horses doing intensive and heavy work. For horses doing lighter work and moving slowly, and for 3- to 4-year-old horses, 12 kg. potatoes per 1000 kg. liveweight daily is a suitable ration. Hansson (1938) gives 5 to 7 kg. potatoes as suitable. On the other hand, according to some writers (Galichnikova and Kusnetsova, 1951 ; Pärn, 1949) both grown and half-grown horses may be given up to 16 kg. per head daily. More may be given of cooked potatoes ; Hansson recommends 12 to 15 kg. boiled potatoes daily and Wrede (1932) 40 kg. steamed ensiled potatoes per 1000 kg. liveweight daily.

The most suitable roots are those relatively high in dry matter. Löwe (1943) uses roots as a substitute for cereal (oat) meal from weaning to 3 years of age without any unfavourable result. Büniger (1944) recommends 20 to 25 kg. roots as the daily maximum for working horses. According to Jespersen (1949), half the ration for horses doing heavy work may be sugar beet, provided the protein content is 50 g. per Sc.F.U. From other Danish experiments (Jespersen, 1939) the conclusion has been drawn that the amount of fodder beet per head daily should be restricted to 25 kg. Hansson (1923) believes that the feeding value of sugar beet for horses is greater when the daily allowance is limited to 10 or 12 kg. Popov (1946)

is more cautious with roots and proposes for heavy horses 6 to 8 kg. carrots or other roots, or at most 15 to 20 kg. Working horses doing light to moderate work, according to Asam (1924) may be given 20 kg. fodder beet or more. He reckons that 5 kg. beet can replace 1 kg. oats.

Root Tops

These too have been given to working horses. Bartsch (1926) says that up to 20 kg. sugar beet leaves can be given to horses doing strenuous work. If the protein requirement is met, 5 kg. sugar beet leaves can replace 1 kg. oats. Temper (1927) came to the same conclusion regarding the use of tops and leaves of roots.

Molasses

Molasses is a valuable feed for horses, especially when it is given with straw as roughage. Popov (1946) approves of the use of molasses, apart from the risk of colic. Views differ on suitable daily allowances. Axelsson (1943) recommends 1.5 to 2 kg. and says that larger amounts cause increased sweating and are laxative. According to Danish experiments (Hofman-Bang, 1917) up to 2.5 kg. molasses can be given to working horses, and 4 parts by weight of molasses can replace 5 of oats. In Germany distiller's potato wash has sometimes been used to feed horses; according to Müller (1931), 40 litres may be given daily.

Cereals

Oats are the concentrate most used for horses and are more important in the feeding of horses than any other feedingstuff. But barley also and other cereals may be used. Jespersen (1949) says the prices of cereals should decide which will be used. Rye should perhaps be excepted because it causes colic. According to Kellner and Fingerling (1924), rye may be used to feed horses but should be mixed with 2 or 3 parts of oats, and Morrison (1937) agrees. On the other hand, Teschner (1927) records that rye in experiments caused no trouble, even when 4.5 to 6 kg. was used for working horses. In his view, rye is a valuable feedingstuff of which 1 kg. can replace 1.20 to 1.25 kg. oats.

Sprouted oats or other germinated grains, at least 1 kg. daily, are believed to have a good effect on stud stallions (Skatkin, 1950).

Oilseeds

Views on the use of oilseeds in rations for horses vary. Jespersen (1949) advises against rapid change to oilseeds since they may cause digestive disturbances. Sunflower seed cake is thought to be the best for horses but, if too much is given, it may cause disorders. Mustard seed cake and cottonseed cake are considered unsuitable for horses and so is hempseed cake. But there are other views: Grigorjev and Feodorov (1946) found that 40 per cent. of the concentrate ration might be of cottonseed cake without ill effect. Of the concentrate mixture in question, 6 to 10 kg. was given daily for 6 months.

Fodder Cellulose

In many countries fodder cellulose was used to feed horses during the second world war. From the studies made it appears that cellulose is an excellent feed and may be used in relatively large amounts, provided the requirements for protein, vitamins and minerals are met. Digestibility coefficients for crude fibre in fodder cellulose, varying from 88.1 to 93.6, are considerably higher than in untreated cellulose (Olsson, 1943a). Edin (1918) found that 0.95 kg. fodder cellulose could replace 1 kg. oats. According to Jespersen (1941b), 3 kg. fodder cellulose is a suitable daily ration, but Olsson (1943b) found in extensive experiments that medium-weight working horses could without harm be given 4.7 kg. fodder cellulose daily and Hvidsten (1945a) states that working horses of 600 kg. live-weight were given up to 5 kg. fodder cellulose daily.

MAXIMUM DAILY ALLOWANCES OF DIFFERENT FEEDINGSTUFFS

Of different feedingstuffs, Popov (1946) gives the following maximum daily quantities for heavy working horses, on the assumption that the feeds are of good quality:

	kg.		kg.
Oats . . .	8.0	Wheat bran . .	4.0
	or more	Malt culms . .	1
Maize, barley . .	6.0	Brewer's draff, dried . . .	3
Rye, wheat . .	4.0		
Sorghum . . .	4.0	Distiller's wash, dried . . .	2
Vetches . . .	2.0	Potatoes . . .	8
Linseed and sunflower seed cake	3.5	Fodder beet . .	12
Hempseed cake	2.5	Carrots . . .	10
Cottonseed cake	1.5	Draff, fresh . .	12 litres
		Silage . . .	8

A similar table has been compiled by Davydova (1946).

CRAMPTON, E. W., FARMER, F. A. and SHAW, R. K. An improved method for determining bomb calorimeter values. *J. Animal Sci.*, 1954, 13, 658-659. [Fac. Agric., McGill Univ., Macdonald Coll., Que.]

The improvement consists in equipping the calorimeter with a manganin-nickel thermocouple and, with a recording potentiometer, making a permanent record of the temperature during the estimation. With 95 samples so examined the standard deviation was 3.0 per cent. of the mean; for about 900 samples with the ordinary type of thermometer it was 3.4 per cent. of the mean.

Saccharides are heated at 100° C. in a sealed tube with acid-regenerated Permutit Q. Monosaccharides, with the exception of ketoses, are detectable after 48 hr. of this treatment. N-acetyl hexosamines are deacetylated by the treatment. The resulting hexosamines must be eluted with HCl. Monosaccharides of carbohydrate-protein complexes are liberated by resin treatment.

H. G. Bray.

39

HARWOOD, V. D. **Analytical studies on the carbohydrates of grasses and clovers. 5. Development of a method for the estimation of cell-wall polysaccharides.** *J. Sci. Food Agric.*, 1954, 5, 270-275. [Dept. Chem., Univ. Edinburgh.]

For previous parts see Abst. 27, Vol. 22; *J. Sci. Food Agric.*, 1952, 3, 494; Absts. 1677, 4047, Vol. 24.

A method is described for the estimation of cell-wall polysaccharides which involves two-stage hydrolysis with H_2SO_4 : pre-treatment with $N H_2SO_4$ to dissolve and hydrolyse the greater part of the hemicellulose fraction, and subsequent treatment with 72 per cent. H_2SO_4 . The resulting monosaccharides are estimated chromatographically. At most 7 per cent. of the monosaccharides was destroyed by the pre-treatment; the agreement in the second stage hydrolysis was within 5 per cent.—D. M. Walker.

40

CHARLET-LÉRY, G., FRANÇOIS, A. and LEROY, A. M. **L'analyse des aliments destinés aux animaux et l'interprétation des résultats qu'elle fournit. [Analysis of feeds destined for animals and interpretation of the results.]** *Ann. Zootech.*, 1952, 1, No. 3, 45-61. [Lab. Zootech., Inst. Nat. Agronom., Paris.]

Defects in the classical system of analysis of feedingstuffs are discussed, particularly those referable to the estimation of indigestible fibre by the Weende method. To overcome them modifications of the system by the use of the following methods for particular constituents are proposed: (1) true cellulose, Kürschner's method (*Tech. Chem. Papier-Zellstoff-Fab.*, 1929, 26, 125), (2) lignin, the method of Mahood and Cable (*J. Indust. Eng. Chem.*, 1922, 14, 933), (3) hydrolysable carbohydrates, by boiling with H_2SO_4 and estimation of glucose, (4) pentosans, by hydrolysis and precipitation of furfural as described by Unger and

Jager (*Chem. Ber.*, 1903, 36, 1222), (5) fraction insoluble in formic acid, by a method based on the work of Guillemet and Jacquot (Abst. 1017, Vol. 15), (6) total pectic substances, as pectic acid, by a method which is briefly summarised.

Analytical data are given in 2 main tables. In the first, comparison is made between values for the fraction insoluble in formic acid (IF) and for the true cellulose (C) and lignin (L) contents of a number of single and mixed feeds. For 20 feeds the mean value of the ratio C + L : IF was 0.98 ± 0.14 , and (IF) is concluded to be a good measure of (C) + (L).

In the second table analytical and digestibility data are given for 31 trials, 9 on cattle, 19 on sheep and 3 on pigs. Of these, 3 on cattle and 10 on sheep were with alfalfa hay alone; the others were with bran or beet pulp or combinations of these. The trials on pigs were with prepared mixed feeds. From the analytical data the contents of "substances organiques ternaires dégraissées" (MTD) were calculated as the differences between total organic matter and the sum of the crude protein ($N \times 6.25$) and fat contents. When the indigestible fibre content (Weende) was plotted against digestibility of organic matter the dispersion was wide, the coefficient of correlation being -0.73 ± 0.06 . If, on the other hand, the ratio lignin content $\times 100$: MTD was used, its coefficient of correlation with digestibility of organic matter was -0.89 ± 0.03 . From the data the equation

$$y = \frac{167}{x} + 52$$

was derived, where y = digestibility of organic matter and x = lignin $\times 100$ / MTD. For all three species and for values of x between 4.8 and 26.6 agreement between calculated and measured digestibility coefficients was good. It is concluded that such estimations give a good measure of the digestibility of a feedingstuff and preclude the making of digestibility trials.—D. Harvey.

41

HELLSTRÖM, N. **The total composition of hay. 2. A study in hemicellulose and cellulose determinations.** *Acta Agric. scand.*, 1954, 4, 209-223. [Inst. Org. Chem., Royal Agric. Coll. Sweden, Uppsala.]

The composition of a G-product of hay, a material almost free from protein, fat and soluble sugars, is reported. The G-product was extracted with alkali varying in strength from 1 to 18 per cent. and also hydrolysed with 2.5 $N H_2SO_4$. The product was analysed for ash, protein and pentosans. The yields and composition of cellulose obtained by the method of Kürschner and Hoffer and of the residues after hydrolysis with acid were estimated.

N.A. and R., January 1955

X-ray investigations of the fat-extracted hay, the G-product and the G-product treated with alkali were made. Cellulose I was shown to be present. The results are compared with previous results obtained with birch wood.—D. M. Walker.

42

MOON, F. E. and ABOU-RAYA, A. K. The lignin fraction of animal feeding-stuffs. 4. The preparation of 'reference' lignin by extraction with ethyl acetoacetate. *J. Sci. Food Agric.*, 1954, 5, 319-323. [Edinburgh and East Scotland Coll. Agric., 13 George Sq., Edinburgh 8.]

For previous parts see Absts. 27, 1206, Vol. 23.

A "reference" lignin was prepared by extraction of the sample with ethyl acetoacetate after pre-treatment with ethanol-benzene and, for young plant materials, acid pepsin. Subsequently, a preliminary treatment with alkali was included also. The purity of the lignin preparation was judged on a high methoxyl and low nitrogen content. Many different plant materials were tested and it was concluded that lignin from young plants is the same as that in mature plants; the greater degree of contamination in young plants causes an apparently low methoxyl content. It is therefore suggested that lignin content can be estimated from total methoxyl content when the conversion factor for different species has been found; this ranged from 5.27 to 5.64, average 5.5, for Gramineae.—D. M. Walker.

BERNHARD, E. Colorimetrische Bestimmung des Ammoniakstickstoffes im Käse. [Colorimetric estimation of ammonia nitrogen in cheese.] *Mitt. Geb. Lebensmittel. Hyg.*, 1954, 45, 115-122. [Milchtech. Inst., Eidg. Tech. Hochschule, Zürich.] French and English summaries.

The Nessler reaction is applied to an extract of cheese with sodium citrate and trichloroacetic acid.

H. G. Bray.

46

MELLETT, S. J., BRODSKY, W. A. and PALMER, L. A rapid modification of the brucine method for determination of nitrates in biological fluids. *J. Lab. Clin. Med.*, 1953, 41, 963-967. [Dept. Paediat., Inst. Med. Res., Sch. Med., Univ. Louisville, Ky.]

Spectrophotometric measurement of the colour developed when a concentrated acid solution of brucine reacted with nitrate enabled amounts of 5 to 30 µg. of the latter per aliquot to be estimated in urine or plasma. Optical density was strictly proportional to the amount of nitrate. The colour was thought to be an oxidation product of brucine.

Nitrite had a similar effect, but as it is generally present in small amounts this was unimportant. Urea did not interfere at the high dilutions used.

It was found possible to estimate nitrate in the presence of nitrite by adding ammonium sulphamate to remove the latter. This method was less sensitive. Nitrite alone could be estimated by a diazotisation process which was unaffected by nitrate.—A. Hepburn.

47

NELSON, J. L., KURTZ, L. T. and BRAY, R. H. Rapid determination of nitrates and nitrites. *Anal. Chem.*, 1954, 26, 1081-1082. [Dept. Agronom., Univ. Illinois, Urbana.]

Nitrite is estimated by diazotising sulphanilic acid and coupling with *l*-naphthylamine, and nitrate by reduction to nitrite with Zn and manganous sulphate.—H. G. Bray.

48

KATZ, J. J. Anhydrous hydrogen fluoride as a solvent for proteins and some other biologically important substances. *Arch. Biochem. Biophys.*, 1954, 51, 293-305. [Chem. Div., Argonne Nat. Lab., Lemont, Ill.]

Anhydrous HF (m.p. -63°, b.p. 19.5° C.) was shown to be a powerful solvent for amino-acids and for proteins, including silk fibroin, collagen, bovine plasma albumin and globulin, egg albumin, cytochrome *c*, ribonuclease, deoxyribonuclease, urease, uricase, pepsin, rennin, trypsin, chymotrypsin, catalase, α -amylase, Hb, insulin and ACTH, chlorophyll and vitamin B₁₂. Hair and keratin were the proteins most resistant to solution.

Most basic groups of bovine plasma albumin recovered from solution appeared to bind 1 molecule of HF. This explained why some proteins recovered from HF dissolved in water to give acid solutions. The solubility and biological properties of these proteins at their isoelectric points are still unknown, and the possibility of denaturation cannot be overlooked.

Many other proteins recovered from solution, including pepsin, bovine plasma globulin, catalase, urease, uricase and silk fibroin, were completely insoluble in water. The addition of hide collagen, glycine, aspartic acid or lysine to an HF solution of bovine plasma albumin conferred water solubility on the product.

Chlorophyll could not be recovered unchanged from solution in HF and catalase and cytochrome c had also lost their biological properties. Vitamin B₁₂ was recovered in a modified form, probably as fluorocobalamin, which retained most of its activity. Insulin retained most of its activity and ACTH appeared to be recovered intact.

A. Hepburn.

Alkaline cellulose treated with chloroacetic acid or N'-2-chloro-N : N-diethylethylamine forms cation- and anion-exchangers, respectively.—H. G. Bray.

51

POLIMENI, R. and TURITTO, P. Determinazione comparativa della frazioni protidemiche con la elettroforesi e con i metodi di salatura. Significato delle differenze. [Comparative estimation of blood protein fractions by electrophoresis and by salting out. Significance of the differences.] *Riv. Ist. sieroterap. ital.*, 1954, 29, 225-242. [Ist. Patol. Med., Univ. Rome.] English summary.

Estimation of the serum protein fractions in 19 healthy subjects with blood protein within normal limits, in whom it might be assumed that the separate protein fractions were of normal physico-chemical composition, showed that there were statistically significant differences between the values obtained by electrophoresis and those obtained by salting out with sodium or ammonium sulphate. Such discrepancies must be attributed to the different methods of fractionation. Examination of 3 groups of pathological cases, 16 with

infectious diseases, 9 with hepatic cirrhosis, and 3 with nephrosis, showed that the discrepancies in the values found by the 3 methods for one particular fraction in healthy subjects could differ from those found for the same fraction in pathological subjects. Moreover, they could show further variations according to the type of disease. Since these discrepancies between the methods in relation to pathological condition are probably based on physico-chemical anomalies of the protein molecule, the simultaneous use of two or three of the methods is advised for a more profound study of the proteins.—M. B. Richards.

[Paper electrophoresis in agricultural biochemistry. 2. Separation and quantitative estimation of fractions of casein prepared by Hammarsten's method.] *Sborn. Čsl. Akad. Zéméd.*, 1954, 27 [A], 355-362. Russian and English summaries.

The proteins of whey were easily separable by paper electrophoresis. Conditions suitable for the fractionation of casein were evolved and the existence of the third γ -form was confirmed. Quantitative evaluation of these electropherograms gave results for the proportions of the 3 forms similar to those reported in the literature as obtained with standard electrophoresis procedures. (From English summary.)—D. Harvey.

Protein is precipitated by ice-cold acetone, separated by centrifuging, treated with versene and dissolved in saline. After electrophoresis the protein fractions are stained with bromophenol blue and the excess dye is removed with acetic acid. The strips are read in an electric densitometer. Under the conditions described no conversion factor for γ -globulin is needed.

H. G. Bray.

CARLSON, L. A. Electrophoretic studies of serum lipoproteins. 1. A description of apparatus and technique for their separation in starch medium. *Acta chem. scand.*, 1954, **8**, 510-520. [King Gustav Res. Inst., Stockholm.]

The components of blood serum were separated on a column containing starch impregnated with water. The serum was driven by pressure into the starch column which was then filled with buffer. The latter was connected by siphon to an electrode vessel, and another electrode in a buffer-filled vessel which surrounded the starch column completed the electrical circuit.

To keep the protein zone narrow for good separation during electrophoresis the protein concentration had to be 2 per cent. or less. The addition of bromothymol blue which coloured the faster-moving albumin enabled the migration to be followed. After electrophoresis the starch column was taken out of the vessel and under a pressure of 10 cm. Hg fractions of constant volume were collected.

The protein, cholesterol and phospholipin contents of the fractions were estimated. The re-

covery of lipids was in all cases 95 to 105 per cent. Neither lipids nor proteins were adsorbed on the starch except in phosphate buffer, and pH and salt concentration had no effect when proteins were forced through the column.

Five distinct lipoprotein components, one slightly faster than albumin, α_1 -lipoprotein, β_1 -lipoprotein, β_2 -lipoprotein and a small component in the γ -globulin fraction in order of decreasing mobility were revealed.—A. Hepburn.

59

ÅGREN, G., DE VERDIER, C. and GLOMSET, J. A study of the phosphorus-containing proteins of cells. 1. The isolation of phosphoserine from the liver proteins of calf and rat. *Acta chem. scand.*, 1954, **8**, 503-509. [Inst. Med. Chem., Univ. Upsala.]

Homogenised calf liver after extraction with cold 10 per cent. trichloroacetic acid had lipids and nucleic acids removed to give the Schneider protein residue. After hydrolysis with HCl and the removal of the acid by evaporation, the hydrolysate was purified by passage through charcoal before separation on a chromatographic column with 0.01 N HCl as eluting agent. An automatic conductivity recording device followed the fractionation and two-dimensional paper chromatography was employed for further study of the fractions.

The livers from 6 adult rats 4 hr. after injection with 1 μ C. 32 P-phosphate per g. bodyweight were treated similarly, but fractionation was followed by means of the radio-activity of the effluent. By evaporating 1 ml. aliquots from each fraction on Al discs and counting the impulses per min. with a Tracerlab's SC-18 Superscaler a more sensitive indication of the fractionation was obtained.

From a fraction of the calf liver protein hydrolysate and a fraction similarly prepared from casein, phosphoserine was crystallised. Rotating crystal photographs from the 2 preparations established their identity. A fraction was obtained probably containing phosphothreonine. Other fractions from paper chromatographic examination contained P compounds, some of which were ninhydrin-positive.

Four main fractions were obtained from the rat liver hydrolysate, the first containing inorganic phosphate, the second peptide-bound P containing both glutamic acid and serine, the third phosphoserine and the fourth very likely phosphothreonine plus small amounts of other P compounds. The amount of phosphoserine P, though $\frac{1}{3}$ rd of the total amount of inorganic P, had a specific activity 5.4 times greater.

The method of phosphoserine preparation is limited because of the hydrolysis of the substance itself presumably along with other more labile P compounds.—A. Hepburn.

DE WAELE, J. and DIAZ CADAVIECO, R. Séparation des aminoacides par chromatographie ascendante monodimensionnelle et leur dosage par photométrie directe sur le papier. [Separation of amino-acids by ascending one-dimensional chromatography and their estimation by direct photometry on the paper.] *Rec. Trav. chim. Pays-Bas*, 1954, **73**, 333-346. [Lab. Vet. Biochem., Univ. Utrecht.]

A quantitative method for amino-acid analysis by the photometric measurement of colour density on a one-dimensional paper chromatogram is described. Phenol at pH 12.0, *m*-cresol and a 1 : 1 mixture of benzyl alcohol and butanol at pH 8.4 were used separately as solvents for 3 different groups of amino-acids. With the same kind of filter paper, the R_F values were approximately constant. A study of optimum conditions was made. The method was found reproducible with a mean error of 4.1 per cent. Results from hydrolysates of egg albumin and horse serum albumin agreed well with those of other methods.—A. Hepburn.

CLAYTON, R. A. and STRONG, F. M. New solvent system for separation of amino acids by paper chromatography. *Anal. Chem.*, 1954, **26**, 1362-1363. [Dept. Biochem., Univ. Wisconsin, Madison 6.]

The mixture is methyl ethyl ketone : propionic acid : water (75 : 25 : 30), the time of development

20 hr., with the ascending technique. Ninhydrin followed by copper nitrate is the detecting reagent. H. G. Bray.

77

ISHERWOOD, F. A. and CRUICKSHANK, D. H. A new method for the colorimetric estimation of amino-acids on paper chromatograms. *Nature*, 1954, **174**, 123-126. [Low Temp. Res. Stat., Univ. Cambridge.]

The solvents recommended are, for neutral amino-acids, a single-phase *n*-propanol-water (80 : 20) mixture, and for acidic amino-acids propionic acid : *tert*-butanol : water (60 : 30 : 10). After use of the second solvent mixture, propionic acid can be removed from the paper by steaming. The amino-acids on the paper after separation are sprayed with a fluoro-dinitrobenzene reagent and heated at 80° C. for 30 min. The spots are then cut out and eluted with an ethanolic borate buffer (pH 8.4), the extract is evaporated and the residue is treated with 91 per cent. H_2SO_4 and the solution extracted with benzene to remove dinitrophenol. The acid layer is cooled with ice and extracted with a mixture of amyl alcohol and benzene. The amino-acid derivatives are extracted into $NaHCO_3$ solution for photo-electric estimation.

H. G. Bray.

78

LEVY, A. L. A paper chromatographic method for the quantitative estimation of amino-acids. *Nature*, 1954, **174**, 126-127. [Hormone Res. Lab., Univ. California, Berkeley.]

Amino-acids are run as dinitrophenyl derivatives, with a two-dimensional technique. The first solvent, used in the ascending method, is toluene : chloroethanol : pyridine : 0.8 *N* ammonia (5 : 3 : 1.5 : 3) and the second, used in the descending method, 1.5 *M* aqueous phosphate buffer ($M NaH_2PO_4$, 0.5 *M* Na_2HPO_4). The spots are cut out and eluted with water and the colour of the eluate is measured spectrophotometrically.

H. G. Bray.

79

ÅKERFELDT, S. A spot area method for quantitative determination of amino acids on two-dimensional paper chromatograms. *Acta chem. scand.*, 1954, **8**, 521-522. [Inst. Res. Org. Chem., Univ. Stockholm.]

The logarithmic relation between concentration and spot area found in one-dimensional paper chromatography by Fisher *et al.* (Abst. 1574, Vol. 18) was proved valid also for 2-dimensional chromatography. The following expression was derived :

$$\log \frac{100 C}{M} = A \cdot F_p$$

where C = spot concentration of amino-acid in $\mu g.$, M = molecular weight of amino-acid, A = spot area in sq. cm., F_p = molar spot area constant.

The last was constant for each amino-acid examined within the investigated range of spot concentrations (10 to 50 $\mu\text{g.}$), but depended on the solvent and filter paper used.

The amino-acids were divided into group A, which contained *isoleucine*, *leucine*, *methionine*, *phenylalanine*, *tyrosine* and *valine*; and group B, containing the remainder. Special solvents were used with each group.

The spots were redrawn on a homogeneous paper and their areas were found by weighing. As different interpretations of spot edges are possible it was recommended that F_p be estimated by each investigator.

The error range of this spot area method for 2 estimations was 2 to 5 per cent.—A. Hepburn.

KIESSLING, H. and PORATH, J. A method of detection of N-dimethylamino acids on paper. *Acta chem. scand.*, 1954, **8**, 859–860. [Inst. Biochem., Univ. Upsala.]

After development the chromatogram is dried and kept in contact with methyl iodide vapour at 35° to 40° C. for 2 hr. The paper is then dried at 100° C. and immersed in ammoniacal 0.1 N silver nitrate and the excess reagent is removed by washing with water. Spots are developed by means of a rapid photographic developer. It is possible to detect unmethylated amino-acids with ninhydrin before detection of methylated acids as described.—H. G. Bray.

90

KORITZ, S. B. and COHEN, P. P. Colorimetric determination of carbamylamino acids and related compounds. *J. Biol. Chem.*, 1954, **209**, 145–150. [Dept. Physiol. Chem., Univ. Wisconsin, Madison.]

The reaction between diacetylmoxime and a ureide group in the presence of an aromatic amine was utilised.

Six ml. of 50 per cent. H_2SO_4 , 0.1 ml. of 1 per cent. aqueous Na diphenylamine-*p*-sulphonate and 0.25 ml. of diacetylmoxime were added to 3 ml. of the unknown and the tube was placed in a boiling-water bath for 10 min. After cooling, 0.25 ml. of 1 per cent. K persulphate was added, the tube was returned to the water bath for 1 min.

Vol. 25, No. 1

and then cooled immediately. Colour developed in the absence of direct sunlight and the optical density was measured at 550 m μ . after 10 min. In this way carbamylamino-acids, citrulline, arginine, hydantoin, urea and other related compounds were estimated colorimetrically.

The colour from carbamyl-L-glutamic acid alone was increased in the presence of histidine or ornithine, possibly because of transcarbamylation, whereby a compound with greater chromogenic value was produced. Sulphur compounds, including cysteine, cystine and methionine, inhibited colour formation.—A. Hepburn.

BARTCH, H. and CHAIKOFF, I. L. A simplified method for determination of lipide- C^{14} in liver. *Proc. Soc. Exp. Biol. Med.*, 1954, **86**, 97-99. [Dept. Physiol., Sch. Med., Univ. California, Berkeley.]

Liver slices are incubated in a 50-ml. Erlenmeyer flask with a centre well fused to the bottom; the flask is sealed with a rubber cap. At the end of the incubation period 30 per cent. KOH is introduced into the centre well to absorb CO_2 and immediately afterwards 5 *N* H_2SO_4 is added to the medium to inactivate the tissue. The incubation medium is then removed by filtration and the tissue is saponified with 1 *M* Na ethylate. After acidification with H_2SO_4 the lipids are extracted with chloroform. For counting, an aliquot of the chloroform solution is mounted directly on an aluminium disc and the solvent is gently evaporated.

The method was examined with a biologically synthesised C^{14} -fatty acid mixture, cholesterol- $4^{14}C$, tripalmitin- $1^{14}C$, alanine- $1^{14}C$, acetate- $1^{14}C$ and glycerol- $14C$ added to separate 500-mg. portions of liver slices; the results obtained were in good agreement with other more laborious procedures. The simplified analysis can be completed within 2 hr.—G. A. Garton.

DEMONT, P. Extension de l'emploi de la liqueur Neusal au dosage de la matière grasse de produits au lait sucrés, du chocolat et du cacao dans d'autres butyromètres que celui à lait. [Extension of the use of Neusal solution for the estimation of fat in sweetened milk products, chocolate and cocoa in butyrometers other than that for milk.] *Mitt. Geb. Lebensmittel. Hyg.*, 1954, **45**, 104-108. [Stat. Lait., Grangeneuve, near Fribourg.] German and English summaries.

Neusal solution was prepared as described in *Molkerei-Lexikon*, 3rd ed., 1952, 452: 100 g. trisodium citrate and 100 g. sodium salicylate were dissolved in 480 ml. distilled water; 172 ml. isobutanol and about 750 ml. distilled water containing 0.1 to 0.2 g. methylene blue were added to make a final volume of 1500 ml., which was filtered if necessary.

Neusal solution dissolves sugar and protein without colour change or precipitation and was used in 2 different butyrometers for the rapid and easy estimation of fat in dried milk, condensed milk, sweetened milk powder, ice-cream, ice-herbet, chocolate and cocoa.—A. Hepburn.

SPEIRY, W. M. A method for the determination of total lipides and water in brain tissue. *J. Biol. Chem.*, 1954, **209**, 377-386. [Dept. Biochem., New York State Psychiat. Inst.]

Brain tissue is homogenised in a special disintegrator. About 500 mg. of the homogenate is weighed from a 2 ml. syringe and added to about 10 ml. acetone in a tared flask; the solvent is removed in a stream of inert gas on a warm-water bath and the drying is completed in a desiccator: the loss of weight represents the water content of the tissue. The lipids are then extracted from the dried tissue with about 10 ml. chloroform-methanol (2:1). After filtration, the solvent extract is freed from water-soluble components by a modification of the washing procedure of Folch *et al.* (*J. Biol. Chem.*, 1951, **191**, 833). The lipid extract is then filtered, the solvents are removed and the residue is dried to constant weight.—G. A. Garton.

106

DOUSTE-BLAZY, L. Fractionnement des lipides du sérum par distribution à contre-courant. [Fractionation of serum lipids by counter-current distribution.] *C.R. Acad. Sci.*, 1954, **239**, 460-462.

Lipid extracts of human serum were fractionated by counter-current distribution in an apparatus of the Craig type. Fifty transfers were made using a mixture of light petroleum and chloroform, 45.5 volumes and 9.1 volumes, respectively, as the hyperphase and a mixture of acetic acid, methanol and water, 21.6, 21.6 and 2.2 volumes, respectively, as the hypophase. The lipids were separated into 9 main fractions of which 6 contained phospholipins; most of the cholesterol was found in one fraction. Esterified fatty acids appeared in most fractions.—G. A. Garton.

SILK, M. H. and HAHN, H. H. 3. The fatty acid composition of South African pilchard oil. 4. The isolation and structure of a hexadeca-tetraenoic acid from South African pilchard oil.

Vol. 55, No. 1

Biochem. J., 1954, **57**, 574-577; 577-582; 582-587. [Nat. Chem. Res. Lab., S. African Com. Sci. Indust. Res., Pretoria.]

For part 1, see Abst. 2753, Vol. 24.

2. Total fatty acids were obtained from the body oil of the South African pilchard (*Sardinia ocellata*, Jenyns) and the corresponding fatty alcohols were prepared by reduction of the intact glycerides with lithium aluminium hydride. The acids were fractionated by the lithium soap and acetone procedure and also by successive removal of more saturated components by formation of urea complexes in ethanol; the second method was also applied to the alcohols.

Urea complex formation yielded an efficient fractionation resulting in a concentrate of acids of high mean unsaturation, rich in the shorter-chain C_{16} and C_{18} acids. The lithium soap and acetone technique resulted in a concentrate of lower mean unsaturation, though it was relatively richer in C_{20} and C_{22} fatty acids. Urea fractionation of the alcohols afforded a concentrate of high average unsaturation rich in C_{16} and C_{20} components.

3. A concentrate of the more highly unsaturated fatty acids of pilchard oil was prepared by the lithium soap and acetone procedure and distilled in a three-stage falling-film molecular still to yield 6 fractions. Portions of each of the fractions were then chromatographed on non-wetting kieselguhr supporting liquid paraffin as the stationary phase, with 60 per cent. aqueous acetone as the developing solvent. Chain length distribution in other portions of the molecular still fractions was determined by reversed-phase partition chromatography (Abst. 2753, Vol. 24) after hydrogenation of the acids over Pd-BaSO₄ catalyst. Urea complex fractionation of a part of the first molecular distillate yielded 4 fractions and a residue, which were examined by reversed-phase chromatography.

A consideration of all the results obtained permitted calculation of the fatty acid composition of one of the fractions which apparently contained a C_{16} tetraenoic acid. The procedures used can reasonably be supposed to have occasioned little or no modification of the acids originally present and further work on these lines should yield information less empirical than that given by traditional ester-fractionation techniques in the evaluation of the composition of marine oils.

4. With the techniques outlined in the preceding abstracts, the C_{16} tetraenoic fatty acid was isolated and characterised as hexadeca-6:9:12:15-tetraenoic acid. That conjugated double bonds were not present was shown by the absence of any selective absorption in the region 220 to 320 m μ . after alkali isomerisation. Oxidation of the acid with KMnO₄ yielded adipic acid and a little glutaric acid. Infrared absorption analysis showed the presence of a terminal vinyl group.—G. A. Garton.

108

GERRITSMA, K. W. Quantitatieve bepaling van de lagere vetzuren in faeces door verdelingschromatographie. [Quantitative estimation of lower fatty acids in faeces by partition chromatography.] *Centraal Inst. Voedingsonderzoek T.N.O., Utrecht*, 1954, *Publ. No. 186*, pp. vi + 86. English summary.

Section 1 of this thesis briefly reviews the history of partition chromatography, section 2 the estimation by that method of the lower fatty acids. The methods of Hiscox and Berridge (Abst. 4623, Vol. 20) and of Reid and Lederer (Abst. 4488, Vol. 21) were tested. Neither was found satisfactory.

In section 3 the literature of colour chromatography is reviewed and tests of the methods of Moyle *et al.* (Abst. 71, Vol. 19), Fairbairn and Harpur (Abst. 3060, Vol. 21) and James and Martin (Abst. 77, Vol. 22) are described. For the estimation of acids from acetic to caprylic Moyle's method is suitable, apart from the long time required for elution and the dependence of the accuracy on the type of silica. That of Fairbairn and Harpur is quick and accurate with lower fatty acids if the silica is good. Methods of preparing silica were next examined. Gas chromatography by the method of James and Martin is an advance in that it includes also in its range formic acid and isomers of the lower fatty acids. The column is of Celite.

Section 4 deals with the isolation of the lower fatty acids by solution in water, treatment with $\text{Ca}(\text{OH})_2$ and filtration, distillation from the acidified filtrate and collection in chloroform or ether. Section 5 deals more specifically with their isolation from faeces and section 6 sets forth the whole process of estimation as applied to faeces. A table, No. 21, gives the content and distribution of lower fatty acids in the faeces of 18 infants fed on breast milk (5), whole acidified cow's milk (9), cow's milk (2) or buttermilk (2). The outstanding differences are the high proportion of lactic acid in the faeces of breast-fed infants and relatively but not so consistently high proportion of acetic and propionic acids in faeces from those fed on cow's milk.

The last section is devoted to the estimation of lactic acid in faeces. Long's method (Abst. 1331, Vol. 16) is chosen and adapted. The oxidation must take place in an atmosphere of nitrogen.

I. Leitch.

109

CROMBIE, W. M. L., COMBER, R. and BOATMAN, S. G. A chromatographic method for the estimation of oleic and linoleic acids in the presence of straight-chain saturated fatty acids. *Nature*, 1954, **174**, 181-182. [Dept. Botany, Univ. Southampton.]

The method is based on the reversed-phase chromatographic technique described by Howard

and Martin (Abst. 1353, Vol. 20). A mixture of pure linoleic and oleic acids was effectively separated on the column, but in mixture with saturated acids linoleic acid was eluted along with myristic acid and oleic acid with palmitic acid. By oxidatively destroying the unsaturated acids with alkaline KMnO_4 (Bertram oxidation) and estimating the remaining saturated acids it was possible to deduce the composition of artificial mixtures containing oleic and linoleic acids.—G. A. Garton.

110

SAVARY, P. Contribution à l'étude de la chromatographie sur papier des acides gras. [Paper chromatography of fatty acids.] *Bull. Soc. Chim. biol.*, 1954, **36**, 927-932. [Lab. Chim. Biol., Fac. Sci., Marseilles.]

The separation of palmitic, myristic, lauric, oleic, capric, stearic and linoleic acids is considered. Untreated filter paper (Whatman No. 1, Schleicher and Schüll Nos. 602 and 598) may be used with different methanol-water mixtures. Permanganate, copper acetate, potassium ferrocyanide and Rhodamine B may be used for revealing the spots, but all are not suitable for use with all papers. Silicone-treated paper may be used with solvent mixtures containing acetone, water and cyclohexane or hexane. For these chromatograms copper acetate and Rhodamine B may be used as detecting agents.—H. G. Bray.

111

PASQUALLI, W. La determinazione degli acidi arachidonico, linolenico e linoleico (vitamina F) nel latte e nel sangue. 2. Dosaggio nel latte. [Determination of arachidonic, linolenic and linoleic (vitamin F) acids in milk and in blood. 2. Estimation in milk.] *Acta vitaminol.*, 1954, **8**, 113-120. [Ist. Clin. Pediat., Univ. Bologna.] French, English, German and Spanish summaries.

After investigation of sources of error, and comparison with a method involving removal of unsaponifiable matter, the following "direct" method was adopted for estimating arachidonic, linolenic and linoleic acids in milk. The unsaturated acids are estimated by extracting them from 5 ml. milk with ether and isomerising their double bonds into conjugated double bonds by heating at 180°C . for 30 min. with KOH in ethylene glycol. They are then dissolved in purified absolute alcohol, and their concentrations are estimated by measuring the absorption at $316\text{ m}\mu$. (arachidonic acid), $268\text{ m}\mu$. (arachidonic and linolenic acids), and $234\text{ m}\mu$. (sum of the 3 acids). The method gives constant and reproducible results, the average errors for single measurements being for linoleic acid 2.5, linolenic acid 25 and arachidonic acid 12 per cent. As the concentration of linoleic acid in milk is relatively

N.A. and R., January 1955

much greater than that of the other 2 acids, its estimation is influenced in a smaller degree by the sources of error previously outlined.

M. B. Richards.

112

CLÉMENT, G., CLÉMENT, J. and LOUEDEC, A. Sur la séparation des esters de cholestérol à partir d'extraits lipidiques de tissus animaux. [Separation of cholesterol esters in lipid extracts of animal tissues.] *Arch. Sci. physiol.*, 1954, 8, 233-250. [Dept. Physiol., Inst. Recherches Cancer Gustave Roussy, C.N.R.S., Univ. Paris.]

Attempts were made to separate cholesteryl esters and glycerides by solvent precipitation of the esters, by selective hydrolysis of the glycerides with castor oil bean lipase and pancreatic lipase and by chromatography on alumina columns. Quantitative separation was achieved only by the chromatographic technique, with light petroleum or carbon tetrachloride as the eluting solvent on alumina activated by heating at 120° C. and benzene on alumina activated by heating at 180° C. Artificial mixtures and the lipids of rat liver, rabbit liver, pig and human sera were effectively resolved into their glyceride and cholesteryl ester components by these methods.—G. A. Garton.

ELSDEN, S. R. and GIBSON, Q. H. The estimation of lactic acid using ceric sulphate. *Biochem. J.*, 1954, 58, 154-158. [Agric. Res. Coun. Unit Microbiol., Dept. Microbiol., Univ. Sheffield.]

Lactic acid is oxidised by ceric sulphate to acetaldehyde, which is distilled in steam into sodium bisulphite solution. The bisulphite compound is decomposed by bicarbonate and acetaldehyde is estimated iodimetrically.—H. G. Bray.

121

WIERZCHOWSKI, Z. and OBUCHOWSKA, I. Ono-
wych metodach oznaczania alkaloidów w
lubinach pastewnych. [New methods for the
estimation of alkaloid content in fodder lupins.]
Rocz. Nauk Rol., 1952, **61**, 159-192. Russian
and English summaries.

Two methods are described. In the first the
alkaloids are removed with a mixture of ether and
chloroform and sparteine is precipitated, dried and
weighed as triplicate. Lupinine is then precipi-
tated with silicotungstic acid and its concentration
is calculated from the amount of silica and tung-
sten trioxide obtained by ashing at 800° C. In the
second method extraction is as in the first but the
alkaloids are both precipitated by silicotungstic
acid and are estimated together.

Slight modifications are suggested when *Lupinus
angustifolius* or *L. albus* is being examined, for
these were found to contain lupanine and appreci-
able amounts of hydroxylupanine. (From English
summary).—D. Harvey.

SWIFT, C. E. The diethylstilbestrol content of tissues
of treated steers, lambs, and poultry. *Food
Res.*, 1954, **19**, 402-409. [Agric. Res. Serv.,
U.S. Dept. Agric., Agric. Res. Centre, Belts-
ville, Md.]

A method, based on the nitrosophenol method of
Gottlieb (*J. Amer. Pharm. Assoc., Sci. Ed.*, 1947,
28, 379; 1948, **27**, 147), was developed for the
estimation of diethylstilbestrol in concentrated
extracts of fat, liver and muscle from treated
animals; the chemical and chromatographic
methods of extraction are described in detail.
Average percentage recovery of known amounts
of diethylstilbestrol was 89.1, 75.3 and 64.2 for
fat, liver and muscle, respectively.

There was no evidence of free diethylstilbestrol
in any of the tissues from a bullock which had had
2 implants of 120 mg. 30 days apart and was
killed 109 days after the first, or from 3 wether
lambs which had had 2 implants of 15, 30 or 60
mg. 30 days apart and were killed 60 to 90 days
after the first, or from cockerels given one 15-mg.
implant in the neck at 6 weeks and killed about a
month later. Small but increasing amounts of
free and combined diethylstilbestrol were found
in the liver and skin, but not the muscle, of
cockerels given one implant of 30, 60 or 12 mg.

Lest diethylstilbestrol bound so as not to be
extracted or estimated by chemical methods should

be present, further work, possibly with radio-active
diethylstilbestrol, is recommended.

BONTING, S. L. (with BLOEMENDAL, H.) Improved
total base determination in serum, urine, and
tissue ash by ion exchange. *J. Lab. Clin. Med.*,
1953, **41**, 968-972. [Netherlands Inst. Nutrit.,
Amsterdam.]

The sulphonic acid cation exchange resin
Amberlite IR 120 in the hydrogen form was found
suitable for the chromatographic estimation of a
total base concentration of 0.005 to 0.01 N in
biological materials.

The resin was kept immersed in water before
and during percolation (0.8 ml. per min.) of the
diluted fluid. The eluate was boiled to remove
CO₂ and titrated with 0.02 N NaOH against
bromothymol blue. No reliable estimation of base
bound to carbonic acid was found possible. The
same column could be used 30 times without
regeneration.

Urine, after preliminary neutralisation, required
a procedure similar to that just described.

The total base of tissues was most accurately
estimated by ashing in a platinum crucible, dis-
solving in HCl and applying the same technique to
the neutralised solution.—A. Hepburn.

125

TERRIER, J. A propos de la volatilité du NaCl et
du dosage du sel et des cendres dans le pain
ordinaire. [Volatility of NaCl and estimation
of salt and of ash in plain bread.] *Mitt. Geb.
Lebensmittel. Hyg.*, 1954, **45**, 111-115. [Lab.
Cantonal, Geneva.] German and English
summaries.

NaCl is not lost below 375° C.; in the presence
of flour its loss during ashing may be prevented by
the addition of sodium carbonate. Procedures are
described for the estimation of salt and of ash in
bread.—H. G. Bray.

126

DENSON, J. R. Flame photometric determination
of electrolytes in tissue and of calcium in
serum. *J. Biol. Chem.*, 1954, **209**, 233-240.
[Dept. Biochem., Army Med. Res. Lab., Fort
Knox, Ky.]

Calcium, Mg, Na and K in tissue were estimated
by measuring the luminosity of the spectra with a
spectrophotometer and a hydrogen burner.

Ashed tissue in 0.1 N HCl was applied to a cation
exchange column so that anions, including phos-
phate, which decreases the luminosity of Ca and
Mg, passed through, and the absorbed cations were

N.A. and R., January 1955

then eluted with 6 N HCl. A correction had to be made for Ca, which was eluted in greater quantity than that added. After evaporation to dryness the eluate was dissolved in 0.1 N HCl and examined spectrophotometrically. By comparison with graphs obtained from a standard solution Ca, Mg, Na and K were estimated. The analysis for each cation was unaffected by the presence of the other 3 in amounts ranging from 5 to 100 times that normally found. Fe, which in certain amounts interferes with the spectra, can be removed by the addition of cupferron to an acid solution of the dissolved ash and subsequent ether extraction of the complex formed.

Serum diluted 1:10 with water and passed through the cation exchange column was similarly analysed, but new standard graphs were required, as the composition of serum differed considerably from that of tissue. The Mg content was too low to be estimated in this way.—A. Hepburn.

KEITEL, H. G. and KEITEL, N. B. Rapid simple method for determination of serum potassium. *J. Amer. Med. Assoc.*, 1953, **153**, 799-800. [Nat. Heart Inst., Nat. Insts. Health, Bethesda, Md.]

150

O'SULLIVAN, M. Rapid determination of urinary sodium. *J. Lab. Clin. Med.*, 1953, **41**, 959-962. [Biochem. Lab., St. Michael's Hosp., Toronto.]

Urinary Na was simply and rapidly estimated by direct measurement in a special centrifuge tube of the volume of precipitate from the reaction with uranyl zinc acetate. At room temperature the K salt was not precipitated. Protein and phosphate were previously precipitated by dilute reagent. A standard calibration curve was used and the accuracy was within $\frac{1}{2}$ g. per litre. Results agreed with those by flame photometer, and the method was faster and required less skill.—A. Hepburn.

151

DESCHREIDER, A. R. and VAN COILLIE, L. Le dosage de l'étain dans les conserves alimentaires. [Estimation of tin in preserved foods.] *Lab. Central, Ministère Affaires Econ., Belgium*, *Publ.* 134, pp. 14. English summary.

The method of Ciesleszky and Lindner (Abst. 123, Vol. 22) for the polarographic estimation of Sn was applied to a number of foodstuffs and found much more accurate, simple and rapid than previous analytical methods.

Cu, Fe and Zn in concentrations of 10 to 20 μ g. per ml. did not affect the estimation of Sn. Pb in the normal small concentrations found in food, 1 to 2 p.p.m. or even up to 5 to 10 p.p.m., did not affect the estimation when Sn was present in normal quantities. When Pb exceeded 5 p.p.m. and Sn was less than 50 p.p.m., 2 methods could be applied: either a standard curve from Pb in 12

per cent. HCl and a colorimetric estimation of Pb by dithizone enabled the concentration of Sn to be estimated from the curve of a mixture containing Sn and Pb, or the Sn could be completely eliminated from the curve by the action of ammonia and ammonium citrate.—A. Hepburn.

152

JONES, G. B. The polarographic determination of zinc and manganese in plant and animal tissues and soils. *Anal. chim. Acta*, 1954, **11**, 88-97. [Div. Biochem., C.S.I.R.O., Univ. Adelaide.] French and German summaries.

The material is wet ashed and Fe and Cu are removed with cupferron. Zn and Mn are then removed together by sodium diethyldithiocarbamate, the complexes are decomposed and the metals are estimated polarographically by a procedure described. Interference by Co and Ni can be prevented by the use of dimethylglyoxime before extraction.—H. G. Bray.

153

HINSVARE, O. N., HOUFF, W. H., WITTEW, S. H. and SELL, H. M. Polarographic determination of zinc in plant materials. *Anal. Chem.*, 1954, **26**, 1202-1204. [Dept. Hortic., Michigan State Coll., East Lansing.]

The zincate wave is used, tetrasodium versenate (ethylenediamine tetra-acetate) being present to prevent co-precipitation of zinc.—H. G. Bray.

Kolorimetrické stanovení aktivity proteolytických enzymů, sledované po oxydaci kobalt-natého substrátu. [2. Colorimetric estimation of the activity of proteolytic enzymes after oxidation of a cobalt substrate.] 3. Jednoduché kolorimetrické stanovení proteolytické aktivity duodenální šťávy s aminokomplexy měďnaté suspence. [3. A simple colorimetric estimation of proteolytic activity of pancreatic juice with amino-complex of copper suspension.] *Sborn. pathofys. tráv.*, 1954, **8**, 68-72. [Res. Inst. Human Nutrit., Prague.]

A method for estimating the digestive activity of pancreatic amylase is described. The action of amylase splits the aldehydic group from the starch. In alkaline solution this group reduces iodine. The remaining I is titrated with thiosulphate after acid is added.

A method of estimating the proteolytic activity of pepsin colorimetrically is described. Cobalt-casein, prepared by mixing equal volumetric parts of 1 per cent. casein (Hammarsten) in 0.1 N HCl with 0.005 M solution of $\text{CoCl}_2 \cdot 6\text{H}_2\text{O}$ or $\text{CoSO}_4 \cdot 7\text{H}_2\text{O}$, is used as a substrate. After incubation for 15 min. 0.15 N HCl and 0.005 M $\text{K}_3\text{Fe}(\text{CN})_6$ are added and the intensity of the colour developed is measured colorimetrically.

A 5 per cent. suspension of dried milk in alkaline acetate is used as substrate for the estimation of the proteolytic activity of pancreatic juice. After incubation for 15 min. 0.15 N NaOH and 0.2 M CuSO_4 are added and the intensity of the colour of the filtered solution is measured colorimetrically.—A. Jančařík (Czechoslovakia).

RAYMOND, W. F. and HARRIS, C. E. The laboratory drying of herbage and faeces, and dry matter losses possible during drying. *J. Brit. Grassland Soc.*, 1954, 9, 119-130. [Grassland Res. Inst., Hurley, Berks.]

Conditions influencing the yield of dry matter from herbage samples were studied. Drying in warm air resulted in losses of up to 5 per cent. as against efficient drying at 100°C. in an oven of new design. In the new oven hot air enters the drying chamber through holes in the shelves on which the sample trays stand. This oven can dry ninety 400 g. herbage samples (80 per cent. moisture) to constant weight in under 6 hr. The size of the sample affects the dry matter yield, since the rate of removal of moisture is more important than the drying temperature.

N.A. and R., January 1955

A "true" dry matter content was estimated by the use of "radio-frequency" heat. With this method the moisture content of 300 g. herbage can be reduced from 80 to from 10 to 20 per cent. in 15 min., the temperature of drying being below 80° C. Comparison of "radio-frequency" heat with the new type of oven showed dry matter losses of 1 per cent. with the latter.

To study losses of nitrogen in the laboratory drying of faeces, a macerated cream of the faeces was made with toluene and water and samples were taken for analysis. A loss of from 5 to 10 per cent. of the N in faeces on oven-drying at 100° C. was found.

The nature of the chemical constituents lost on drying is discussed.—D. M. Walker.

BABAD, J., PINSKY, A. and SHARON, N. Calculation of total solids in milk of cows in Israel by Richmond's formula. *Indian J. Dairy Sci.*, 1954, **7**, 98-100. [Agric. Res. Stat., Rehovoth, Israel.]

This paper describes work done to test the applicability of Richmond's formula in Israel over that period of the year when subtropical conditions prevail. A number of samples were taken from individual cows and total solids were estimated by evaporation. The results obtained by this method were used as a criterion to test Richmond's formula, and indicated that the formula tended to over-estimate total solids under the conditions described, on the average by 0.35 per cent.—A. W. Boyne.

165

HEINEMANN, B., COSIMINI, J., JACK, E. L., WILLINGHAM, J. J. and ZAKARIASEN, B. M. Methods of determining the per cent. total solids in milk by means of the lactometer. *J. Dairy Sci.*, 1954, **37**, 869-876. [Producers Creamery Co., Springfield, Mo.]

166

BISHOP, S. J. and MITCHELL, J. H. (Jr.) Determination of the solubility index of spray dried eggs. *Food Res.*, 1954, **19**, 367-372. [Quartermaster Food and Container Inst. Armed Forces, Chicago, Ill.]

An improved method used at the Quartermaster Food and Container Institute since 1947 is described. Egg powder, 1.5 g., is added to 50 ml. of

0.9 per cent. NaCl solution, shaken thoroughly and centrifuged in a 16-in. centrifuge at 2000 r.p.m. for 10 min. Five ml. of the supernatant solution are mixed with 10 ml. Esbach reagent (20 g. citric acid and 10 g. picric acid in 1 litre of water) and centrifuged at 2000 r.p.m. for 10 min.; the volume of precipitate is read and recorded as the solubility index. Tests with 8 samples in 2 laboratories showed better reproducibility than the method previously in use, and the results were in closer agreement with those of organoleptic tests; also, the time required was halved.—W. M. Deans.

167

HISZPAŃSKA, C., ZAŁĘSKI, J. and PŁOŃSKA, H. Kasze. Oznaczanie przemian i kwasowości. [Groats: estimation of degree of extraction and acidity.] *Rocz. Państwowego Zakł. Hig.*, 1954, **5**, 179-186. Russian and English summaries.

Samples numbering 120 of groats from different grains were examined. The upper limits recommended for ash content as a percentage of dry matter are for semolina 0.6, crushed barley groats 1.5, roasted buckwheat groats 2.2 and millet groats 1.4. The upper limit for total acidity is 3° for semolina and 5° for barley and buckwheat groats. For the estimation of total acidity an extract with boiling water was most suitable, and for buckwheat a mixture of bromothymol blue with phenolphthalein as indicator gave the best colour change. (From English summary.)—D. Harvey.

CLINICAL AND EXPERIMENTAL

175

POOLE, J. C. F. Haemoglobin standard. *Lancet*, 1954, 267, 116-117. [Sir William Dunn Sch. Pathol., Oxford.]

The estimate by Bernhart and Skeggs (Abst. 344, Vol. 13) of the percentage of Fe in Hb is considered the best of existing estimates and at 0.340 per cent. can alone be regarded correct to 3 significant figures. The British Standards Institution Haldane Hb colour standard recalculated from this figure instead of 0.334 is 14.5 g. per 100 ml. blood instead of 14.8 and this new value is recommended.—A. Hepburn.

176

FLOOD, F. T., MANDEL, E. E., OWINGS, R. H. and FEDERSPIEL, C. F. Newer standards in hemoglobinometry. *J. Lab. Clin. Med.*, 1954, 43, 897-904. [Communicable Dis. Centre, Pub. Health Serv., U.S. Dept. Health.]

Drabkin's method for estimating oxyhaemoglobin, based on the empirical finding that the ratio of optical densities of 2 independent colour standards is reasonably constant for all photoelectric photometers of the same type, was investi-

gated with 19 instruments of 3 different makes. (For details of the method see Drabkin, *Spectroscopy: Photometry and Spectrophotometry*, "Medical Physics", Vol. II, pp. 1039-1089, Year Book Publishers, Inc., Chicago, 1950.)

The use of the cupric ammonium sulphate standard is recommended for filter photometers, but not for spectrophotometers because of the inherent greater width of the spectral band.

177

VAN KAMPEN, E. J., VOLGER, H. C. and ZIJLSTRA, W. G. De bepaling van het haemoglobinegehalte van bloed. [Estimation of the haemoglobin content of blood.] *Nederl. Tijdschr. Geneesk.*, 1954, 98, 2442-2446. [Lab. Physiol. Chem., Rijks Univ., Groningen.]

The following methods of estimating Hb were compared: by estimation of Fe by digestion with H_2O_2 , not H_2O , as catalyst and titration in CO_2 against $TiCl_3$ with HCNS as indicator; by estimation as cyan-methaemoglobin or oxyhaemoglobin in the Beckman spectrophotometer; by the Sahli method; and in the Sica haemoglobinometer. The Sahli method involves a relatively large error,

N.A. and R., January 1955

standard deviation 1.2 g. per cent.; the Sica method, if the instrument is accurately calibrated, is better, S.D. 0.50 g. per cent. as compared with oxyhaemoglobin 0.38 and TiCl_3 0.44 with cyanmethaemoglobin as standard.—I. Leitch.

178

GEMZELL, C. A. and SÖSTRAND, T. Method for determination of total amount of haemoglobin and blood volume in small animals. *Acta physiol. scand.*, 1954, 30, 369-374. [Dept. Clin. Physiol., Karolinska Sjukhuset, Stockholm.]

The animal is placed in a glass chamber of about 1 litre capacity and a known volume of carbon monoxide (about 0.4 ml.) is introduced. Ten min. later 5 litres of CO-free air are passed through the chamber and collected and the CO content is estimated. The Hb content of the animal is calculated in terms of its CO-combining power and the blood volume, using a factor. No sample of blood is taken.—H. G. Bray.

READ, R. C. Studies of red-cell volume and turnover using radio-chromium: description of a new "closed" method of red-cell-volume measurement. *New Engl. J. Med.*, 1954, 250, 1021-1027. [Lab. Surg. Res., Peter Bent Brigham Hosp., Boston, Mass.]

The conditions under which ^{51}Cr is taken up by whole blood are considered and results obtained with human subjects are described.—H. G. Bray.

184

DEMPSEY, M. E. and WILSON, R. H. Normal human oxygen saturation of the arterial blood as determined by gasometric analysis. *J. Lab. Clin. Med.*, 1954, 43, 790-797. [Veterans Admin. Hosp., Minneapolis, Minn.]

Arterial blood samples from normal men were used for gasometric analysis by several different techniques to estimate blood oxygen content and oxygen capacity, and sources of error were investigated.

The neutral ferricyanide method was found to give a more accurate measure of oxygen content than the alkaline ferricyanide technique, since the latter solution does not absorb the CO_2 completely. A tonometer coated with silicone gave results for oxygen capacity similar to those obtained in the Van Slyke chamber, but the latter method is considered less subject to error.

By the neutral ferricyanide content and chamber capacity methods the normal arterial oxygen saturation is estimated as 97.9 per cent. with S.D. ± 1.14 and range 96.1 to 99.9, and with neutral ferricyanide and tonometer capacity the corresponding figures are 97.8 ± 1.15 , 96.3 to 100 per cent.—D. Duncan.

185

BOYD, W. C. Error in calibration of commercial BMR machines. *J. Appl. Physiol.*, 1954, 6, 711-715. [Dept. Biochem., Sch. Med., Boston Univ., Mass.]

Methods are discussed for correction for the error of 0.5 to 0.6 per cent. which is caused by the assumption, in calibrating B.M.R. machines, that the patient metabolises only fat and carbohydrate. H. G. Bray.

186

SENDROY, J. (JR.) and CECCHINI, L. P. Determination of human body surface area from height and weight. *J. Appl. Physiol.*, 1954, 7, 1-12. [Div. Chem., Naval Med. Res. Inst., Nat. Naval Med. Centre, Bethesda, Md.]

Two grid diagrams, of which enlarged copies can be had from the authors, are reproduced, one giving body surface area in sq. m. from the sum and quotient of weight (kg.) and height (cm.), the other a simpler one derived from it with weight and height as co-ordinates. They are claimed to be at least as reliable as the calculations of Boyd (Abst. 1350, Vol. 6) and more so than the DuBois chart. They are based on 123 sets of data from the subjects of the classic researches of DuBois and DuBois and Benedict and from Eskimo and white subjects recently studied by Rodahl and Edwards (Absts. 1831, 4507, Vol. 23) and 129 additional sets from Boyd's compilation.—W. M. Deans.

189

HUTCHINSON, J. C. D. A simple climatic chamber for physiological work with poultry. *J. Agric. Sci.*, 1954, 44, 361-368. [Poultry Res. Centre (A.R.C.), W. Mains Rd., Edinburgh.]

The design of an inexpensive climatic chamber which is transportable and in which the temperature, humidity and rate of movement of the air can be independently controlled is described in detail. Temperature and humidity may be varied over a wide range of values above external air conditions. For lower values a refrigeration system, to which brief reference is made, is employed.

The average rate of air movement is normally 20 ft. per min., and the range of variation about this figure is small. The chamber, designed primarily for poultry, is just large enough to accommodate 6 cages within the working space, but larger chambers may be built on the same principles.—J. D. Pullar.

EBERT, E. F., ROSEBOOM, B. B. and DALE, H. E. "Deperitonealization" of the wall of the rumen. *Amer. J. Vet. Res.*, 1954, 15, 405. [Dept. Vet. Med., Sch. Vet. Med., Univ. Missouri, Columbia.]

The procedure was designed to allow repeated penetration of the rumen by needles or trocars without contamination of the peritoneum or the need for a permanent fistula.

The subject was a young Jersey cow. With paravertebral anaesthesia in the standing position an 8-in. vertical incision was made in the left paralumbar fossa. An area of parietal peritoneum 3 in. to each side of the incision and the corresponding area of visceral peritoneum on the rumen wall were scraped with a dull knife to produce mild hyperaemia. The rumen was then anchored to the abdominal wall at the 4 corners of this area by single large interrupted sutures and the incision was closed.

From 4 weeks after the operation repeated stab wounds were made into the rumen, without evidence of peritoneal infection.—D. Duncan.

NICHOLS, R. E. An inflatable plug for small rumen fistulas. *Amer. J. Vet. Res.*, 1954, 15, 246. [Dept. Vet. Sci., Univ. Wisconsin, Madison.]

The plug has the advantages of being fairly simple, easily removed and capable of being inflated to seal the fistula opening. It has withstood rumen pressures of several lb. per sq. in. in sheep without leakage. It consists of a plastic stem with a flange to lie against the skin. Around the stem below the flange is fitted a piece of rubber from an ordinary toy balloon, sealed to it at its upper and lower ends. An air passage from the outside runs through the stem, emerging again within the balloon. To seal the plug in position, air is forced in through this passage to inflate the balloon.—W. A. Greig.

MAINLAND, D. (with MAINLAND, R. B.) Evaluation of the skeletal age method of estimating children's development. 2. Variable errors in the assessment of roentgenograms.

Vol. 25, No. 1

Pediatrics, 1954, 13, 165-173. [Dept. Anat., Dalhousie Univ., Halifax, N.S.] Spanish summary.

For part 1, see Abst. 1579, Vol. 24.

The aim of this investigation was to evaluate accurately the variable error of an observer in estimating the skeletal age of children from X-ray photographs of the hand, and to find whether an error allowance should be made for the following: (1) atlas used (Todd or Greulich and Pyle), (2) age of child, (3) sex, (4) differences between skeletal and chronological age, (5) differences between X-ray photographs of different children, (6) differences between photographs of the same child, (7) quality of photographs, (8) speed of assessment. The variable error was studied on 1124 readings of 326 films from 233 children aged from 16 months to 17 years; 79 of the photographs were reproductions from Macy's *Nutrition and Chemical Growth in Childhood* (Absts. 2944, Vol. 12; 3256, Vol. 22), 90 were of healthy children in an orphanage in Halifax and the rest were obtained during a nutrition survey in Halifax.

A variable error of 3 months was found in the Macy photographs with either the Todd or the Greulich and Pyle atlas; a variable error of 3 months was also found in the nutrition survey children, with only the Greulich and Pyle atlas, and of 4 months in the orphanage children, with both atlases. In order to obtain 95 per cent. probability with a variable error of 3 months the observer must affix an error of ± 8.3 months, and for a deviation of 4 months the observer must allow ± 11.1 months.

On completing 1200 readings the observer's practice lapsed for a year. Re-assessment of random photographs revealed a systematic difference from the previous readings of the same films with the same atlases of approximately 3 months. D. Benzie.

MERKEL, R. A., SORESENSEN, D. K., KOWALCZYK, T. and BRAY, R. W. A technique for securing tissues to study muscular fat deposition in swine. *Cornell Vet.*, 1954, 44, 3-6. [Dept. Animal Husb., Univ. Wisconsin, Madison.]

A biopsy technique is described by which fat and muscle samples for histological and chemical analyses can be obtained from animals on feeding trials.

An incision $1\frac{1}{2}$ to 2 in. long is made parallel and close to the vertebral column of an anaesthetised pig. After the depth of back fat is measured, a rectangular sample measuring about $1\frac{1}{2} \times \frac{3}{4} \times \frac{3}{8}$ in. is removed from the longissimus dorsi muscle; haemorrhage is controlled by gauze tampons, and if necessary by ligation of large vessels. This operation was performed on 60 pigs with normal surgical precautions and after-treatment, and in none did any secondary complication ensue.

KRAYBILL, H. F., HINER, R. L. and FARNWORTH, V. M. The relation of organ weights to lean

body mass and empty body weight in cattle. *J. Animal Sci.*, 1954, 13, 548-555. [U.S. Dept. Agric., Bur. Animal Indust., Agric. Res. Admin., Beltsville, Md.]

The relation between lean body mass, empty bodyweight and the weights of the liver, kidney, spleen, heart and pancreas was determined by statistical analyses of data from 165 cattle of varying weights and ages. The weights of all organs were positively correlated with both empty bodyweight and lean body mass. It was concluded that the weights of all organs studied would prove of equal value in estimating empty bodyweight and lean body mass. The hypothesis that liver weight is unique as an index of the weight of the lean body mass was not confirmed.—J. N. Aitken.

COOKING, STERILISATION AND PRESERVATION OF FOOD

213

MOSSSEL, D. A. A. and NELEMANS, F. A. De toevoeging van chemische verbindingen zonder voedingswaarde aan levensmiddelen, gezien van het standpunt der volksgezondheid. [Addition of chemical compounds without food value to foods, from the standpoint of public health.] *Nederland. Tijdschr. Geneesk.*, 1954, 98, 2577-2588. [Centraal Inst. Voedingsonderzoek T.N.O., Utrecht.] English summary.

A list is given of commonly used "additives without food value" under the headings: preservatives, anti-oxidants, anti-staling agents, pigments, flour improvers, thickeners, emulsifiers, sweeteners and miscellaneous. Views differ from the one extreme that nothing should be added to the other that anything is permissible that is not obviously harmful.

Techniques for the testing of these additives and their limitations are discussed. Some have been shown to have extremely undesirable long-term effects, e.g., hyperplasia of the testis from some glycols used in essences, thyroid dysfunction from some sweetening agents. With reference to the question of supervision, compulsory declaration of additions may not be of much help to the average consumer but might be useful to doctors. Metabolism tests with labelled test substances may provide more reliable information than the usual pharmacological tests (cf. Deuel, *Food Technol.*, 1953, 7, 381).—I. Leitch.

214

GERRITSMAN, K. W. Polymere fosphaten toegevoegd aan levensmiddelen. [Polymeric phosphates added to foods.] *Voeding*, 1954, 15, 293-303. [Centraal Inst. Voedingsonderzoek T.N.O., Utrecht.] English summary.

Polymeric phosphates have displaced organic acids, e.g. citric acid, in the processing of spreading cheeses; they are used in baking powders and in the meat processing industries to improve the colour of meat and prevent the clotting of blood for sausage.

The chemistry of these phosphates is reviewed. Their metabolism is not properly understood. Danger may arise from contamination with arsenic or fluorine.—I. Leitch.

215

KALOYERREAS, S. A. The effect of pasteurization on the stability of phosphates can be used as a test for heated milk. *Science*, 1954, 120, 111-112. [Dept. Agric. Chem., Louisiana State Univ., Baton Rouge.]

Pasteurisation for 30 min. at 62°C. reduced the pH of milk; continuation of the treatment for 30 min. more made no further change. Titration curves of rennet sera indicated that the heat treatment produced an increase in mono- and a decrease in di-calcium phosphate. The phosphate is considered to be more stable in heated than in raw milk. A similar change in pH with heating was reproduced with mixtures of the phosphates,

and it is suggested that the change is the result of a new equilibrium between the mono- and di-calcium salts established by a reaction between the di-calcium phosphate and carbonic acid.

These effects of heat on the pH and on the stability of the phosphates of the serum can be used to differentiate heated from raw milk.

PATTON, A. R., SALANDER, R. C. and PIANO, M. Lysine destruction in casein-glucose interaction measured by quantitative paper chromatography. *Food Res.*, 1954, 19, 444-450. [Chem. Sect., Colorado Agric. Exp. Stat., Fort Collins.]

Casein was subjected to different treatments, namely, autoclaving with or without water and/or glucose at 120° C., autoclaving with 6 N HCl for 6 hr. and enzymic digestion with 1 per cent. trypsin for 10-5 hr. Lysine was estimated by paper chromatography and comparison with a standard lysine curve.

After trypsin digestion the percentage of lysine left was as follows: casein untreated, 6.0; casein autoclaved without glucose, 5.2; casein-glucose mixture untreated, 3.2; and casein-glucose mixture autoclaved, 1.2.

Autoclaving alone had no effect on the lysine content of casein, nor did acid hydrolysis in the presence of 1 per cent. glucose cause significant destruction of lysine although other amino-acids were significantly affected at the 0.01 level. A greater amount of glucose did cause lysine destruction, which was most severe when casein was autoclaved with moist heat. Autoclaving for 4 hr. with different amounts of moisture caused only slight destruction of lysine.

When casein was treated with 2:4-dinitrofluorobenzene and the hydrolysate was chromatographed a yellow spot due to the ϵ -dinitrophenyl derivative of lysine appeared. When autoclaved with steam in the presence of glucose no dinitrophenyl derivative was formed; this was evidence that the free amino-groups in the lysine residues had been blocked, presumably by a carbonyl-amino reaction.

SCHORMÜLLER, J., BIEN, K. J. and WINTER, H. Beiträge zur Biochemie der Käsebereitung. 4. Das Verhalten des Tyrosins im Verlauf der Reifung. [Biochemistry of cheese ripening. 4. Behaviour of tyrosine during ripening.] 5. Das Verhalten des Tryptophans im Verlauf der Reifung. [5. Behaviour of tryptophan during ripening.]

SCHORMÜLLER, J. 6. Methionin, Cystin und Schwefelwasserstoffschwefel im Verlaufe der Reifung von Sauermilchkäse. [6. Methionine, cystine and hydrogen sulphide sulphur during the ripening of sour milk cheese.] *Ztschr. Lebensmittel-Untersuch. Forsch.*, 1954, 98, 411-24; 99, 98-109; 214-227. [Inst. Lebensmittelchem., Tech. Univ., Berlin, Charlottenburg.]

4. In continuation of previous work (Abst. 4263, Vol. 24), tyrosine was estimated in samples of sour skimmed milk cheese by the method of Bálint (Title 4210, Vol. 8) and that of Thomas (Abst. 2896, Vol. 14). The results are presented in tables and graphs.

In normally ripened cheese, tyrosine in the true protein and water-soluble protein fractions tended to increase during ripening; in accelerated ripening it decreased; free tyrosine was not found except in stored unsalted curd.—W. M. Deans.

5. Tryptophan was estimated by the method of Bates (Title 1356, Vol. 7) or that of Spies and Chalmers (Absts. 46, Vol. 18; 4359, Vol. 19; 3108, 4611, Vol. 20). Under normal conditions no free tryptophan appeared in the residual N fraction. Only with excessively long ripening, or breakdown of casein under conditions leading to complete spoiling of the cheese, was any considerable amount of this amino-acid liberated. Moreover, under normal ripening conditions there was no question of any diminution of biological value occurring through destruction of tryptophan. In rapid ripening there was an increase of tryptophan in the water-insoluble protein, coupled with a decrease in the water-soluble protein fraction. This confirms previous findings that rapid ripening is inferior from the nutritional standpoint to the normal ripening procedure.

6. The constituents were estimated by a micro-method previously developed (Schormüller and

N.A. and R., January 1955

Ballschmieter, *Ztschr. anal. Chem.*, 1951, **132**, 1 and 6). Under normal ripening conditions there was no destruction of methionine or cystine. Only with excessively prolonged ripening did the methionine content fall off. Conversely, within the framework of the present investigations, there was no indication of biogenesis of the amino-acids in question. The percentages of both in the total N remained very constant, so that under the conditions tested there was no question of any reciprocal transformation of the 2 substances. As a rule H_2S -sulphur was about evenly divided between the true protein and residual N fractions, and this distribution showed no appreciable change during ripening.—M. B. Richards.

GINGER, I. D., WACHTER, J. P., DOTY, D. M., SCHWEIGERT, B. S., BEARD, F. J., PIERCE, J. C. and HANKINS, O. G. Effect of aging and cooking on the distribution of certain amino acids and nitrogen in beef muscle. *Food Res.*, 1954, **19**, 410-416. [Div. Biochem., Amer. Meat Inst. Found., Chicago, Ill.]

Nitrogen, arginine, leucine, tyrosine, histidine, glutamic acid and lysine were estimated before and after ageing for 2 weeks, in raw and cooked beef rib steak, in the drippings from the meat and in the N.P.N. fraction, in the last two both before and after acid hydrolysis.

Cooking caused a sharp decrease in the soluble protein N present, some free amino groups being liberated as a result of proteolysis. Ageing increased the amino-N content of the N.P.N. fraction of both raw and cooked meat. Raw meat had only a slight loss of total N in the drippings, irrespective of ageing; this was chiefly N.P.N. with 14 to 25 per cent. free amino-N.

Ageing had little effect on the arginine, leucine and tyrosine content of the samples except in the drippings and the N.P.N. fractions, where there was a slight increase. Less than 3 per cent. of the total of these amino-acids was found in the N.P.N. fractions. Hydrolysis of the drippings and the N.P.N. fractions showed leucine, tyrosine, glutamic acid and lysine to be present in bound forms. The N.P.N. fraction contained up to 32 per cent. of the total histidine after hydrolysis, compared with 3 per cent. before hydrolysis. Microbiological analyses with carnosine as a reference standard indicated histidine to be present also in bound forms other than the peptide carnosine.

AUERBACH, E., WANG, H., BATES, V., DOTY, D. M. and KRAYBILL, H. R. A histological and histochemical study of beef dehydration. 3. Influence of pre-cooking. *Food Res.*, 1954, **19**, 420-432. [Amer. Meat Inst. Found., Univ. Chicago, Ill.]

Cylinders of *Biceps femoris* from a commercial grade carcass were pre-cooked to internal temperatures of 60°, 76.6° and 93.3° C. in a beef tallow bath and dried for 16 hr. at 45° C. under vacuum and at 70° C. in an air oven; duplicate cylinders were electrolysed after pre-cooking and before dehydration. Large blocks of tissue were also cooked and cylinders removed for further treatment. Methods for rehydration, moisture estimation, electrolysis, histological and histochemical treatment were as before (Absts. 176, 2827, Vol. 24).

From the degree of subsequent rehydration of the samples the best internal temperature of pre-cooking was found to be 76.6° C. for only the electrolysed block cylinder group. Electrolysed block cylinder samples dehydrated at 70° C. reached a higher level of rehydration than similarly treated samples dehydrated at 45° C., regardless of cooking temperature. The calculated correlation coefficient between moisture content and muscle fibre diameter for all the data obtained was 0.612. In the dehydration of unground beef tissue pre-cooked had no advantage over raw meat. G. F. Garton.

224

SWICKARD, M. T. and HARKIN, A. M. Percentage relationships of raw carcass weights and yield of cooked edible portion for young Beltsville Small White turkeys. *Poultry Sci.*, 1954, **33**, 775-779. [Bur. Human Nutrit., Agric. Res. Admin., U.S. Dept. Agric.]

Fifty-two Beltsville Small White turkeys were used in this study, twenty 14-week-old toms, twenty 16-week-old hens and twelve 26-week-old toms. The carcasses were stored at 35° F. before evisceration and were then frozen for 1½ to 3½ months at 0° F. The roasting times varied with size and degree of fatness of the bird. After cooling and skinning, the meat was stripped from the bones, that from the base of the neck to the end of the ribs being reckoned as light and that from the legs, thighs and back below the ribs as dark meat.

The dressed weight as a fraction of liveweight was 89.2 per cent. for 14- to 16-week-old birds irrespective of sex and 91.4 per cent. for 26-week-old toms. The ready-to-cook weights indicated that the hens (68.8 per cent. of the liveweight) were significantly heavier than the young toms; older toms gave a still higher weight at 71.8 per cent. of the liveweight. The proportionately higher ready-

to-cook weight of the older birds was due to a larger amount of fat; the difference between the young toms and hens was due to different viscera, neck and gilet weights.

Expressed as a percentage of liveweight, the cooked edible portion of 14-week-old toms was 36.3 per cent., of 16-week-old hens 37.7 per cent. and of 26-week-old toms 39.9 per cent., all differences being significant at the 5 per cent. level. Yield of light meat from 14-week-old toms was 26 per cent. of ready-to-cook weight, from 16-week-old hens 27.4 per cent. and from 26-week-old toms 28.1 per cent. Shrinkage during roasting was greatest in the older birds, 25.3 per cent., significantly higher than in the younger birds, 21.4 per cent.—M. J. Head.

MCDONALD, C. E. and MILNER, M. The browning reaction in wheat germ in relation to "sick" wheat. *Cereal Chem.*, 1954, 31, 279-295. [Dept. Milling Indust., Kansas State Coll., Manhattan.]

Studies of samples of wheat germ stored under different conditions provided further evidence in favour of the conclusion of Cole and Milner (*Cereal Chem.*, 1953, 30, 378) that the brown pigmentation of the germ found in "sick" wheat is due to a browning (Maillard) reaction. The colour change is favoured by high temperature and high moisture content; it sets in before mould growth, and is accompanied by a decrease in peptisable protein.

OLAFSON, J. H., CHRISTENSEN, C. M. and GEDDES, W. F. Grain storage studies. 15. Influence of moisture content, commercial grade, and maturity on the respiration and chemical deterioration of corn. *Cereal Chem.*, 1954, 31, 333-340. [Dept. Agric. Biochem., Minnesota Agric. Exp. Stat.]

Studies of respiration with continuous aeration at 30° C. over a 10-day period in an apparatus previously described (Title 3023, Vol. 15) and of

mould count, viability, fat acidity and reducing and nonreducing sugars in samples of white or yellow dent maize differing in moisture content, U.S. grade or stage of maturity at harvesting showed that respiration is accelerated when the moisture content exceeds about 14.5 per cent. and that maize respire more rapidly than wheat (see Abst. 1554, Vol. 17), and confirmed earlier findings that unsound grain or grain harvested immature is more liable to heat or deteriorate on storage.

BARTNIK, J. and TRZEBSKA, I. Wpływ stopnia rozdrobnienia i typów przemian na strawność mąk razowych. [The influence of the degree of disintegration and type of milling on the digestibility of whole-grain flours.] *Rocz. Państwowego Zakł. Hig.*, 1954, 5, 187-194. Russian and English summaries.

The types of milling studies were stone, hammer, roller, hurricane and "vitahan" and the degree of disintegration was determined by the use of standard sieves. Digestibility trials were made with rats.

The degree of disintegration of the grains, wheat and rye, had no effect on the digestibility of organic matter or crude protein of the flours but in relation to the type of milling may have some effect, depending on the dimensions of the free bran particles. The digestibility of the organic matter of wheat flours was about 1 per cent. and of protein 13 per cent. higher than for rye flours. (From English summary.)—J. S. Thomson.

MORAN, T., PACE, J., and McDERMOTT, E. E. The lipids in flour. Oxidative changes induced by storage and improver treatment. *Nature*, 1954, 174, 449-452. [Res. Assoc. British Flour Millers, Cereals Res. Stat., St. Albans.]

The oxidation or peroxide value of whole flour suspensions was studied by adapting the thiobarbituric acid method of Wilbur *et al.* (*Arch. Biochem.*, 1949, 24, 305). Treatment of 80 per cent. extraction flour with agene (NCl₃) or chlorine dioxide (ClO₂) resulted in an immediate small rise in the peroxide value.

Light petroleum extracts of treated and untreated flour were prepared by percolating the solvent through a column of the flour. When the extracts were kept in stoppered flasks in the light at room temperature the thiobarbituric acid value

N.A. and R., January 1955

increased and eventually insoluble, polymer-like material was deposited; the value increased most rapidly in the extracts from flours treated with agene or ClO_2 . Other solvents (carbon tetrachloride, chloroform, benzene and ether) were similarly used to extract the lipids. In all cases the extracted material auto-oxidised in the light more quickly than did the light petroleum extracts; in the dark all the extracts were comparatively stable.

The total reducing value of the unsaponifiable matter of the lipids of a range of treated and untreated flour was estimated by the method of Tošić and Moore (Abst. 346, Vol. 17). Treated flours yielded unsaponifiable matter with reducing values much lower than those obtained with untreated flour lipids; it is suggested that this test could be used to decide whether or not a given flour had been treated. Although flour stored in air for several months showed only a relatively small fall in reducing value, a steady rise occurred in the peroxide value of the extracted lipids.

MORAN, T., HUTCHINSON, J. B. and THOMLINSON, J. The flavour of porridge. *Nature*, 1954, 174, 458. [Res. Assoc. British Flour Millers, Cereals Res. Stat., St. Albans.]

It is alleged that porridge nowadays is often insipid and lacking in flavour and aroma, possibly because English consumers are too readily satisfied by the effect of adding sugar instead of salt. The flavour of porridge meal or flakes is developed during the original kilning process, and in this note on work which will be published more fully elsewhere it is stated that the optimum conditions correspond to gentle drying of the oats from their usual moisture content of about 17 down to about 8 per cent., followed by toasting for 20 min. in a current of air at 150° C. The substances responsible for the desirable "nutty" flavour are not known. Despite traditional belief, the furnace gases play no part in its development.

OLSEN, G. E. Fresh vs. pre-processed vegetables. Comparative cost and availability. *J. Amer. Dietetic Assoc.*, 1954, 30, 762-765. [Dining Halls, Univ. Washington, Seattle.]

The vegetables studied were fresh or frozen broccoli, carrots, peas, spinach, fresh or dried onions, and fresh or pre-peeled potatoes. Trimming waste and preparation time and cost were estimated, and quality and palatability were judged.

Fresh broccoli, peas, onions and spinach were less economical than the pre-processed vegetables because of the time required in preparation. Diced frozen carrots and pre-peeled potatoes were more expensive than the unprocessed vegetables. Pre-processed vegetables were more uniform in quality than the fresh. Frozen broccoli and peas were preferred to fresh, but fresh carrots, onions and spinach were preferred to the pre-processed vegetables.—F. C. Aitken.

DEUEL, H., SOLMS, J. and DENZLER, A. Klärung von Fruchtsäften mit polymeren Basen. [Clarification of fruit juices by means of polymeric bases.] *Mitt. Geb. Lebensmittel. Hyg.*, 1954, 45, 73-84. [Agrik.-Chem. Inst., Eidg. Tech. Hochsch., Zürich.] French and English summaries.

Methods of clarifying fruit juices are briefly reviewed and the precipitation of pectins is discussed. By addition of the polymeric base polyethyleneimine to apple, bramble, currant, cherry, orange, tomato or white grape juice, pectins were satisfactorily precipitated, and with them other substances causing turbidity; viscosity was greatly reduced, with little change in pH. Since the optimum amount differs with different juices, preliminary tests must be made. Further studies are in progress.—W. M. Deans.

AXELSSON, J. and SUNDEBY, H. Våxlingen för ensilagens pH-värde, särskilt under tiden närmast efter fodrets inläggning. [Changes in the pH of silage, especially immediately after the fodder is ensiled.] *Kgl. Lantbruksakad. Tidskr.*, 1954, 93, 218-224. English summary.

The measurements were on silage made in glass jars of 1 to 2 litres capacity, with lucerne, clover and grass, ensiled with A.I.V. solution, acid salts, molasses or Kofa salt (calcium formate and sodium nitrite). The addition of acid as A.I.V. solution or a mixture of sulphate and phosphoric acid rapidly reduced pH: buffering caused a subsequent rise and fermentation a second fall which continued until bacterial activity ceased. Molasses and Kofa salt accelerated fermentation but the bases contributed by Kofa salt kept pH relatively high. Other things being equal the pH of lucerne silage was above that of clover, and that of grass was lowest.

HARWOOD, V. D. Analytical studies on the carbohydrates of grasses and clovers. 6. Changes in the cell-wall polysaccharides during the ensilage of perennial ryegrass with a high protein and low soluble-carbohydrate content. *J. Sci. Food Agric.*, 1954, 5, 276-277. [Dept. Chem., Univ. Edinburgh.]

For the methods used to estimate the polysaccharides see Abstr. 39, Vol. 25.

Experimental silages were prepared from perennial ryegrass where the ratio of crude protein to water-soluble carbohydrates was 4.5:1. In the preparation of the silages some were inoculated with a culture of lactobacilli. Changes in pH and in the content of individual carbohydrates were followed over a 2-month period. A bad silage resulted (pH 6.6 after 2 months) and was explained chemically by the rapid disappearance of soluble sugars and failure of the acid-producing bacteria to attack the cell-wall polysaccharides. No free arabinose or xylose was found and the cellulose content was unchanged. It was concluded that the lactobacilli attack the pentosans after the depletion of the free sugars, since significant losses of araban and xylan occurred.—D. M. Walker.

SHEPHERD, J. B., WISEMAN, H. G., ELY, R. E., MELIN, C. G., SWEETMAN, W. J., GORDON, C. H., SCHOENLEBER, L. G., WAGNER, R. E., CAMPBELL, L. E., ROANE, G. D. and HOSTERMAN, W. H. Experiments in harvesting and preserving alfalfa for dairy cattle feed. *U.S. Dept. Agric. Tech. Bull.* No. 1079, February 1954, pp. 147. [Washington, D.C.]

This comprehensive bulletin gives the results of experiments made at Beltsville, Md., over a period of 5 years to determine the relative merits of harvesting a hay crop of alfalfa as field-cured hay, barn-dried hay, wilted silage or artificially dehydrated hay with special reference to labour and equipment required for harvesting and storage by each method, the length of exposure of the crop to the weather after it is cut, losses of dry matter and nutrients during harvesting and storage, the yield, composition and quality of the fodders produced, their value for growth and milk production and their effect on the vitamin A content of the milk and butterfat produced.

Field losses by different methods of harvesting all indicated a relationship between the length of time forage was exposed to the weather and the percentage of losses of dry matter, carotene, protein and leaf. Loss of carotene was highest and the loss was most rapid immediately after the forage was cut, the rate diminishing as a logarithmic function of time. Losses of other constituents were linear functions of time. Storage losses were least for hay that was barn-dried with supplemental heat, slightly greater for field-cured hay and dehydrated hay, and still greater for hay that was barn-dried without heat and for wilted silage. In each method of harvesting loss of crude fibre was least. For the field-cured hay and for barn-dried hays storage losses of dry matter, N-free extract and carotene were greatest in hay stored with the highest moisture content.

Combined harvest and storage losses were lowest for dehydrated hay, only slightly higher for wilted silage and for barn-dried hay with supplemental heat and increasingly higher for barn-dried hay without supplemental heat, hay that was field-cured without damage by rain, and rain-damaged, field-cured hay.

Dehydrated hay and wilted silage were more palatable than the other forages.

The wilted silage, barn-dried hay and field-cured hay given at the rate of 1 to 1½ lb. daily to vitamin-D-depleted calves provided an adequate supply of vitamin D.

Experiments with cows showed that it was possible to produce forages sufficiently high in carotene, when liberally fed during the winter, to produce winter butter with a yellow colour and vitamin A potency approaching those of summer butter.—J. S. Thomson.

ACCARDI, F. Indagini sulla perdita in valore nutritivo nella formazione di fieno-silo con *Hedysarum coronarium* L. ed *Avena sterilis* L. [Losses of nutrients in ensiling hay of *Hedysarum coronarium*, L. and *Avena sterilis*, L.] *Zootec. Vet.*, 1954, 9, 178-181; 212-219.

N.A. and R., January 1955

The first part of the paper is a theoretical discussion on hay-silage and on methods of comparing nutritive values.

Herbage was wilted and ensiled at about 50 per cent. moisture, with the addition of salt at 2 per cent. of the dry matter. After 6 months the silage was acceptable to cattle. The moisture content had fallen to 43.6 per cent. Comparison between the herbage at the time of ensiling and the silage itself, after corrections to allow for loss of ammonia and volatile substances in analyses, gave the following differences in percentages of dry matter: crude protein 10.41 and 10.35, crude fat 1.13 and 1.13, ash 7.66 and 8.43, cellulose 34 and 35, N-free extract 46.80 and 45.09. The nutritive values in starch units were calculated as 41.49 and 30.60, and in forage units as 59.33 and 43.76. It was estimated that the loss of digestible protein was 6 per cent., but part of the N was present as ammonia and probably still available to the ruminant. The total loss of nutritive value, about 35 per cent., is probably less than would have occurred if the herbage had been stored as hay.—D. Duncan.

243

LEROY, A. M. and ZELTER, S. Z. Recherches sur l'efficacité alimentaire des marcs de pomme fermiers. 2. Dégradation de la matière alimentaire d'un marc de pomme fermier frais, conservé par ensilage. Action inhibitrice de certains conservateurs chimiques. [Feeding value of cider apple residues. 2. Decrease in feeding value of apple residues conserved as silage. Inhibitory action of some chemical preservatives.] *Ann. Zootech.*, 1954, 3, No. 2, 95-107. [Lab. Recherches Zootech., Inst. Nat. Agronom., Paris.]

For part 1, see Abst. 5330, Vol. 24.

The apple pulp, containing 26.2 per cent. dry matter and 6.22 per cent. soluble sugar, was distributed in silos of about 1 c.m. capacity holding about 1 ton of pulp. The silos were drained and were lined with bituminised paper. Preservatives added to each layer in aqueous solution, with quantities used per ton of pulp, were formic acid, 2 litres of 10 per cent. solution; salt, 10 kg.; or SO_2 , 420 g. in 7.5 per cent. solution. The silos were opened for sampling after 193 or 213 days.

The pH of the pulp changed little, and the loss of protein was negligible. In each silo there was a considerable increase in lipids, accounted for by the formation of volatile fatty acids from carbohydrate. In silos without added preservative 30.5 per cent. of the nutrients was lost, including 28.6 per cent. of the cellulose and 39.8 per cent. of the non-nitrogenous matter, with 89.8 to 95.7 per cent. of the soluble sugars. Alcohol was the chief product, with some acetic and lactic acids, but no butyric acid.

Vol. 25, No. 1

Salt was of no value in preventing the loss of nutritive value. Sulphurous acid reduced the loss of cellulose but did not prevent the loss of sugars, and even more alcohol was produced than in the control silos. Formic acid was the most valuable preservative; with it the loss of sugar was only 39.9 per cent. of the control and that of organic matter 58.6 per cent. The alcohol content was reduced by 61 per cent. and the organic acids by 32.5 per cent.—D. Duncan.

SKRIBAN, A. I. Khimiko-biologicheskaya obrabotka grubyykh kormov. [Chemico-biological treatment of coarse fodder.] *Priroda*, 1954, No. 2, 93-95. [Inst. Chem., Acad. Sci., White Russian S.S.R.]

The chemico-biological treatment of coarse fodders developed by the Institute of Chemistry greatly increased the feeding value of these fodders, and only insignificant amounts of HCl were used. The chopped fodder is placed in a vat (tank or trough) and covered with a weak solution of HCl (0.1 to 0.2 per cent.). The receptacle is then tightly covered and steam is driven in. Saccharification is complete in 3 hr.; the hemicellulose part of the polysaccharides is easily hydrolysed, with the formation of sugar. Straw and other coarse fodders have their feeding value raised to approach that of succulent feeds.

In the second stage of the treatment the saccharified fodder with the liquid is used to grow feed yeast. After cooling the treated fodder is placed in a fermentation vat, which is inoculated with feed yeast, and at a temperature of 27° to 30° C. air is bubbled through continuously for 20 to 24 hr. The protein, fat and carbohydrate contents of the fodder then approach those of concentrated feeds.

Addition of salt to solutions of HCl increased the degree of saccharification of vegetable tissues by from 2.5 to 3.5 per cent. Addition of cobalt chloride increased also the output of reducing sugar.

The yeast used was *Manila murmanica*. At the start of fermentation the nutrient salts essential for the growth of the yeast were added, 150 g. superphosphate and 80 g. ammonium sulphate per 100 kg. saccharified fodder. The straw used was that of winter cereals, which had become unfit for cattle feeding in its natural state. During saccharification all the harmful organisms which would otherwise have caused severe stomach upsets in the cows were destroyed.

Increased yields of milk, up to 15 per cent., were noticed when cows were given the improved fodder.

The hydrolysed straw chop, without the liquid, was also found useful as silage, both alone and

when added to greenstuff (beans) difficult to ensile.—H. Scherbatoff.

STEINBERG, M. P. and ORDAL, Z. J. Microbiological fat production. Effect of fermentation variables on rate of fat formation by *Rhodotorula gracilis*. *J. Agric. Food Chem.*, 1954, **2**, 873-877. [Dept. Food Technol., Univ. Illinois, Urbana.]

Experiments were undertaken to find the effects on fat production by *Rhodotorula gracilis* of different experimental conditions when the fat-producing phase was separated from the multiplication or growth phase of the culture. Details of apparatus, preparation of full-grown yeast cultures and analysis of the fat produced are given. The fat content was expressed as the ratio of weight of fat to weight of non-fat yeast solids ("fat ratio"). The term "fat rate" was applied to the number of g. fat per 100 g. non-fat dry yeast formed per hr.

Between pH 3.0 and 8.5 the fat rate varied linearly and increased from 2.1 to 3.1. Reducing the temperature from 28° to 22° C. halved the fat rate. To find out if accessory growth factors influenced fat formation, studies were made on yeasts grown in media without yeast extract. Although the growth of the cells was poorer than on normal media which contain yeast extract the subsequent fat production was just as great. In a second experiment the medium without yeast extract was inoculated from a culture of the yeast already grown in yeast-extract-free medium. Again fat was formed. It is concluded that this

yeast's requirement of yeast extract for fat formation must be very small or zero. The cells grown in yeast-extract-free medium had a very high fat content before the fattening phase of the experiment was started. It is suggested that the lack of yeast extract limited the growth of the cells and excess carbohydrate was then used for fattening during what corresponded to the growing phase in normal medium. The cations sodium and iron were tested in a similar way; neither was necessary for fat formation.

Increasing the sugar concentration of the medium from 4 to 40 per cent. by weight showed that up to 20 per cent. no increase in fattening was obtained. Above 20 per cent. the fat content decreased. Glucose, fructose and a mixture of equal quantities of glucose and fructose were equally good as substrates for fat formation. Ethanol and sodium acetate in concentrations equimolar in carbon content with the sugars gave less fat formation than the sugars. The pH of the acetate medium rose from 7.55 to 9.12 after 38 hr.; that of all other media fell to about 5.5. Replacement of 10 per cent. of the sugar on a carbon basis with glycerol or sodium acetate was tried. Glycerol made little difference to fat formation. The pH of the acetate medium was initially adjusted to 4.78. Cell growth was inhibited. The results are discussed with those of other workers.

OLONOVSKI, M. and MONTEUIL, J. Étude chromatographique des polysaccharides du lait de femme. [Chromatographic study of the polysaccharides of human milk.] *C.R. Acad. Sci.*, 1954, 238, 2263-2264.

Human milk from which protein and lipid had been removed was evaporated to dryness and the residue was dissolved in boiling methanol to get rid of most of the lactose. The resulting mixture of polysaccharides was crystallised and separated by chromatography on paper with different solvents and by elution with alcohol on a charcoal-Celite column.

Fourteen polysaccharides were isolated and the hydrolysates purified by passage through an anion exchange column were separated chromatographically to give the relative proportions of each component. Eight polysaccharides contained both glucose and galactose; of these 6 also contained fucose and 3 also acetylglucosamine. Polysaccharides were not found in cow's milk but were found in appreciable quantities in human milk and increased in amount from the first to the seventh day after birth.—A. Hepburn.

250

MONTEUIL, J. Structure de deux triholosides du lait de femme. [Structure of two trisaccharides in human milk.] *C.R. Acad. Sci.*, 1954, 239, 510-511.

The application of paper chromatography to a solution of human milk containing a mixture of polysaccharides resulted in isolation of 2 trisaccharides both with a reducing group and strongly laevorotatory. The acid hydrolysates after purification by anion exchange were chromatographed and glucose, galactose and fucose identified in the ratio 1:1:1.

Partial hydrolysis with 0.5 NH_4SO_4 for 2 to 15 min. and chromatography of the hydrolysate revealed in both cases fucose and a substance with an R_F value corresponding to lactose. Hydrolysis of the latter yielded galactose and glucose. After oxidation of the trisaccharides with bromine and then hydrolysis only galactose and fucose were found, showing that glucose was the terminal reducing group. The β -configuration in the trisaccharides was demonstrated by the action of specific enzymes.

The following structure for the 2 trisaccharides was therefore proposed: either β -fucosido- β -galactosido-glucose or β -galactosido- β -fucosido-glucose.

Samples of milk from cows were pooled separately and analysed 3 times weekly before and after the cows were put out to grass in the spring.

The mean butterfat content increased by 10 per cent. from an average of 34.4 g. per 1000 for the last 3 weeks in confinement to a maximum of 38.0 after 8 days. Total N constituents increased rapidly by 8 per cent. from 30.8 g. per 1000 to a maximum of 33.3 after 1 week of grazing. Casein

increased by 9 per cent. to a maximum after 1 week; other proteins had a maximum increase of 16 per cent. after the first 2 days. All the increases mentioned varied widely with different cows and lasted only about 2 weeks. N.P.N. decreased throughout the experiment.

Milk production was not significantly increased, and as a good quality feed was supplied for the last few months in confinement the increase in the protein content was considered to be due to the spring grass, possibly to its oestrogen content, which is very low or nil in summer and autumn.

BERGE, S. Forholdet protein/fett og fettfritt tørrstoff/fett ved ensidig utvalg av kyr etter produksjon av mjølkefett. [The ratio protein: fat and non-fat solids: fat in the restricted selection of cows on their production of milk fat.] *Tidsskr. norske Landbruk*, 1954, 61, 211-219.

The data on composition of the milk from the college herd (see Abst. 1383, Vol. 25) are used with those of Janse (Abst. 3261, Vol. 20) for Holstein milk and of Davis (Abst. 1411, Vol. 23) to establish that as milk fat rises, solids-not-fat rise also but at a lower rate. Most of the increase in solids-not-fat, at least in Jersey milk, is in protein. It is suggested on the basis of Swedish observations on inheritance of capacity to produce fat and protein (Larsson *et al.*, 12th Internat. Dairy Congr., 1949, p. 287) that by selection for protein as well as fat more rapid improvement in the quality of milk would have been achieved.—I. Leitch.

257

THOMAS, W. R., HARPER, W. J. and GOULD, I. A. Free fatty acid content of fresh milk as related to portions of milk drawn. *J. Dairy Sci.*, 1954, 37, 717-723. [Dept. Dairy Technol., Inst. Nutrit. Food Technol., Ohio State Univ., Columbus.]

Milk samples were obtained at different stages of lactation from cows of the Ayrshire, Guernsey, Jersey, Holstein and Brown Swiss breeds and analysed for free fatty acids. The samples were drawn in 3 portions with about 85 per cent. of the total amount in the second portion.

The general trend was for the first drawn portion to show the highest free fatty acid content and the last-drawn (third) portion to show the lowest content. In individual cows late in lactation, however, there was a tendency for all 3 portions of milk to contain about the same amount of free acid. The first, second and third samples from individual cows showed a wide variation from day to day.—G. A. Garton.

258

EL-KATIB, M. M. T. Relation of stage of lactation to volatile and unsaturated fatty acids of Egyptian cow and buffalo butterfat. *Indian J. Dairy Sci.*, 1954, 7, 101-109. [Agric. Chem. Dept., Fac. Agric., Cairo Univ.]

Butterfat samples were prepared from milk obtained at weekly or fortnightly intervals during the whole lactation period of 3 cows and 5 buffaloes. The Reichert, Polenske and iodine values of the fats were estimated.

The Reichert value of buffalo butterfat, average 29.18, was higher than that of cow butterfat, average 25.14, throughout the lactation periods, though both values declined gradually as lactation progressed. The Polenske values of cow butterfat were higher than those of buffalo butterfat. The average iodine values of cow and buffalo butterfats were 33.01 and 32.10, respectively; both rose slightly towards the end of lactation.

MHASKAR, V. V. and BANERJEE, B. N. Component acids and the probable glycerides of the milk fat obtained from cottonseed-fed buffaloes. *Indian J. Vet. Sci.*, 1954, 24, 93-104. [Dept. Biochem., Indian Inst. Sci., Bangalore.]

Milk fat was prepared from the milk of buffaloes which had been given a diet which included 1 lb. of a mixture of cottonseed 75 and concentrate mixture 25 per cent. for every 3 lb. milk produced. The fat was separated into 4 fractions by crystallisation from acetone at low temperatures and the fatty acid composition of each fraction was estimated by the ester-fractionation technique.

The probable composition of the glycerides was computed to be trisaturated 25.5, disaturated-monounsaturated 40.0, monounsaturated-diunsaturated 27.2 and triunsaturated 7.3 moles per cent. The component fatty acids of the whole fat included higher percentages of oleic, palmitic and stearic acids and lower percentages of lower saturated acids than were found by Achaya and Hilditch (Abst. 3269, Vol. 20) in milk fat from buffaloes on a normal diet.—G. A. Garton.

260

HOLWERDA, K. Variaties in het citroenzuurgehalte van melk, geleverd aan zuivelfabrieken in Friesland. [Variations in citric acid content of milk delivered to dairy factories in Friesland.] *Nederlands Melk Zuivelijdschr.*, 1954, 8, 115-124. English summary. [Bond Coöp. Zuivelfabriek, Friesland, Leeuwarden.]

Citric acid was at a minimum between November and January with a rapid decline in November. These changes were associated not with change from pasture to stall and stall to pasture but with

stage of lactation. Mean values in summer were of the order of 1.6 to 1.8 g. and in winter 1.3 to 1.4 g. anhydrous citric acid per litre.—I. Leitch.

261

KERN, A. Le lait de brebis en Israel. [Ewe's milk in Israel.] *Lait*, 1954, 34, 257-276.

In this review of many analytical studies over a number of years the average composition of ewe's milk in Israel is compared with that of cow's and goat's milk. The percentage composition of ewe's milk is given as water 81.6, fat 7.5, protein 5.6, lactose 4.4 and salt 0.9. The monthly variations in the composition of bulk samples and also the composition of ewe's colostrum are recorded. Tables and graphs are presented showing the monthly variations in the composition of ewe's milk fat, as indicated by iodine value, saponification value, Polenske and Reichert values, refractive index and melting-point.—G. F. Garton.

262

KASHCHANOV, L. V. O razviti i i pol'zovanii molochnoi produktivnosti konevodstva i proizvodstva kumysa. [The development and exploitation of milk production in horse management and the preparation of koumiss.] *Konevodstvo*, 1953, No. 12, 19-24.

A survey of articles which have appeared in this journal on the production and utilisation of koumiss. Mare's milk has a high vitamin content; the vitamin C content is higher than in vegetables and fruit and the vitamin A content is higher than in cow's milk. The fat globules are small and therefore easily assimilable. Kirghiz mares had an average yield of from 17.3 to 30.8 litres daily, average 22.6 litres. The milk yield of mares of heavy breeds during a lactation period was over 3000 litres, and that of mares of racehorse breeds 2000 to 3000 litres, with daily yields of 18 to 22 litres.

It has been shown that as much as 1000 to 2000 litres per season of the milk of high-yielding mares can be used for the manufacture of koumiss without harm to the foals, provided these are given sufficient concentrates and succulent fodder.

It is recommended that the quality of mare's milk from different breeds should be studied. A study should also be made of the effect on the chemical composition of the milk, yield and length of lactation period of different systems of management, feeding and milking.—H. Scherbatoff.

263

KURAMSHINA, M. G. K voprosu o molochnom konevodstve. [The problem of horse management for milk.] *Konevodstvo*, 1953, No. 11, 40-41. [Microbiol. Sect. Acad. Sci., Kazakh SSR.]

Vol. 25, No. 1

It is considered that in order to place the production of mare's milk on a sound footing and spread among the population a valuable subsidiary curative and dietetic product, it is essential to have a Central Scientific Research Institute with a koumiss laboratory, divided into medical, milk technological, and zootechnical departments.

H. Scherbatoff.

264

KHERASKOV, S. G. Moloko verbyuditz i produkty ego pererabotki. [Camel's milk and products prepared from it.] *Konevodstvo*, 1953, No. 11, 35-37. [Chkalov Agric. Inst.]

According to data from the former All-Union camel breeding station the average annual milk yield of 15 dromedaries was 1500 to 2000 litres, that of one Bactrian camel 800 to 1200 litres, with a fat content of 4.5 to 7 per cent. The average annual production of milk fat by dromedaries was 140 to 180 kg., a record annual milk yield during a lactation period of 15 to 18 months being 2500 to 3000 litres. The sugar content of camel's milk is over 5 per cent.

Several products are prepared. *Shuart* and *agaran* are prepared by curdling the milk; the latter is considered a cure for anaemia. *Chal* and *shubat* are fermented drinks. *Chal* is highly nutritious. *Shubat* resembles koumiss and is considered a cure for tuberculosis, anaemia and other diseases.—H. Scherbatoff.

265

ROSS, V. and MOORE, D. H. An alcohol-soluble protein in the milk of mice (RIII). *Biochim. biophys. Acta*, 1954, 15, 50-53. [Dept. Biochem., Coll. Phys. Surg., Columbia Univ., New York.] French and German summaries.

Samples of milk were obtained 10 to 12 days after parturition from groups of RIII mice, i.e., carriers of mouse mammary tumour agent, some of which had palpable tumours. Centrifuging at 1000 g and at 14,000 g for 45 min. at each speed removed lipids, cells and calcium-casein complex. Addition of absolute ethanol to the supernatant fluid and further centrifuging yielded another supernatant from which the single protein was precipitated by anhydrous acetone. Its chemical reactions and electrophoretic behaviour are described. Leucine, valine, proline and glutamic acid were the strongest spots on a paper chromatogram of a hydrolysate. Cow's milk given the same treatments yields none of this protein.

D. Harvey.

Eggs

267

SAUTER, E. A., HARNS, J. V., STADELMAN, W. J. and McLAREN, B. A. Seasonal variations in quality of eggs as measured by physical and functional properties. *Poultry Sci.*, 1954, **33**, 519-524. [Dept. Poultry Sci., State Coll. Washington, Pullman.]

The eggs used in this study were obtained from Single Comb White Leghorn and New Hampshire hens of similar age, each given 2 different rations, one producing a light yolk and the other a dark yolk. The eggs were collected at different seasons and examined at weekly intervals after storage at 70° F., and 65 to 70 per cent. relative humidity. The 5 physical constants measured were albumin index, albumin score, yolk index, yolk colour and albumin pH; the functional and flavour properties of the eggs were judged from flavour of eggs raw, cooked in shell and poached, texture and grain, penetrometer values and angel food value.

The first 3 physical constants showed winter eggs to be superior to summer eggs when stored from 1 to 5 weeks in spite of an overall general decline in quality during storage. The other physical constants were unaffected by season and storage. The quality of the products prepared from stored eggs was directly related to the physical quality of the egg. Better products were obtained from winter eggs than from summer eggs and from fresh eggs than from stored eggs.

HARTMAN, L., SHORLAND, F. B. and McDONALD, I. R. C. Occurrence of *trans*-acids in animal fats. *Nature*, 1954, **174**, 185-186. [Fats Res. Lab., D.S.I.R., Wellington, N.Z.]

Infrared absorption analysis revealed the presence of *trans*-fatty acids in ruminant depot fats (ox, sheep, deer); none was detected in the body fats of rat, horse or rabbit and only a trace in the fat from pigs which had received skimmed milk.

Although no appreciable amount of *trans*-acids was found in pasture lipids, about 9 per cent. of *trans*-acids was found in the fatty acids isolated from the rumen contents of pasture-fed sheep. It is suggested that these *trans*-acids may arise by bacterial action in the rumen.—G. A. Garton.

271

SWERN, D., KNIGHT, H. B. and EDDY, C. R. *Trans*-octadecenoic acid content of beef fat. Isolation of elaidic acid from oleo oil. *J. Amer. Oil Chem. Soc.*, 1952, **29**, 44-46. [E. Res. Lab., Philadelphia, Pa.]

Three samples of freshly rendered beef fat from the pleural and kidney regions and samples of the "oleo" oil and "oleo" stearine obtained from one of them were examined for the presence of *trans*-acids, using CS₂ solutions of the fats, in a Beckman IR-3 infrared spectrophotometer. The *trans*-acid content, calculated as tri-elaidin, of the pleural and kidney fat was from 5 to 8 per cent., of the "oleo" oil 6 per cent. and of the "oleo" stearine about 10 per cent. The increased amount of *trans*-acids present in the "oleo" oil and "oleo" stearine is tentatively attributed to oxidatively-induced *cis-trans* isomerisation, though the widely held assumption that *trans*-acids occur only in traces in beef fat is no longer tenable in view of the findings on the freshly rendered fat. Both elaidic and vaccenic acids were isolated from the "oleo" oil fatty acids by a combination of treatments, including low-temperature crystallisation, lead salt segregation and fractional distillation of methyl esters of the fatty acids.

It is suggested that the naturally-occurring *trans*-acids may arise as a result of oxidative *cis-trans* isomerisation coupled with double bond shift (reactions known to take place in oxidising fat systems), or by a simple oxidative *cis-trans* isomerisation without double bond shift of oleic or other

isomeric *cis*-octadecenoic acids which may be present in beef fat.—G. A. Garton.

272

HANSEN, R. P., SHORLAND, F. B. and COOKE, N. J. Isolation of *n*-heptadecanoic acid from hydrogenated mutton fat. *Nature*, 1954, 174, 39. [Fats Res. Lab., D.S.I.R., Wellington.]

Fractional distillation *in vacuo* of the methyl esters of fatty acids from hydrogenated mutton fat yielded fractions of saponification equivalent about 284. When these fractions were converted to the corresponding acids and submitted to low-temperature crystallisation several grams of a purified acid were obtained, the analytical characteristics of which (equivalent 270.2, m.p. 61.2°–61.4° C., and X-ray long spacing 4.08 mμ.) were consistent with those of *n*-heptadecanoic (margaric) acid.—G. A. Garton.

273

GUNSTONE, F. D. and RUSSELL, W. C. **Animal fats. 3. The component acids of ostrich fat. 4. The component acids of crocodile fat.** *Biochem. J.*, 1954, 57, 459–461; 462–465. [Dept. Chem., Univ. Glasgow.]

3. Fat was obtained from an adult male ostrich (*Struthio camelus*) which had been kept in a zoo on a diet of pasture and whole maize. The mixed fatty acids were separated into groups of differing unsaturation by low-temperature crystallisation from methanol and then each group was analysed by the ester-fractionation technique.

The major component acids were palmitic 24.8, oleic 39.8 and octadecadienoic 17.1 per cent. by weight; myristic, stearic, arachidic, hexadecenoic, polyethenoid C₁₆, octadecatrienoic and higher unsaturated acids were also present. The findings are discussed in relation to published analysis of the fats of other birds.

4. Analyses were made in the same way of the fats of two crocodiles: one animal was an adult Estuarine crocodile (*Crocodylus porosus*) which had been kept in captivity for 20 years and fed on whole dead piglets and the other (*Crocodylus niloticus*) was a Tanganyikan specimen which had been living in the natural state.

Each fat contained similar amounts, 33 to 35 per cent., of saturated fatty acids, consisting mainly of palmitic acid, with smaller quantities of lauric, myristic, stearic and arachidic acids, but the fats differed in the proportions of unsaturated acids present. The fat of *C. niloticus* was noteworthy for its high content of hexadecenoic acid, 14.4 per cent. by weight.

The findings are discussed in relation to the composition of the depot fats of amphibians and reptiles.—G. A. Garton.

OLLEY, J. and LOVERN, J. A. The lipids of fish. 5. The lipids remaining in the flesh of the haddock after extraction by acetone and ethanol-ether. *Biochem. J.*, 1954, 57, 610–619. [D.S.I.R., Torry Res. Stat., Aberdeen.]

Haddock flesh which had been previously extracted with acetone and with a mixture of ethanol and ether (Absts. 4042, Vol. 23; 229, 1642, Vol. 24) was successively extracted with boiling ethanol-benzene (2:1), boiling chloroform-methanol (1:1) and pyridine at 100° C.

All 3 extracts consisted mainly of non-lipid material which was removed by partition between chloroform and water. The purified lipid extracts were separated into acetone-soluble and acetone-insoluble materials; further separation of the acetone-soluble lipids yielded acidic and neutral fractions. All the fractions obtained were complex mixtures, analysis of which was impossible with the small amounts available.

A table is given showing the composition of the total lipids of haddock flesh; lecithin is the major component (43 per cent.), and triglycerides (2.4 per cent.) are quantitatively among the least important constituents.—G. A. Garton.

275

PATHAK, S. P., PANDE, G. D. and MATHUR, S. S. The component acids of the fats of some Indian fresh-water fishes. *Biochem. J.*, 1954, 57, 449–453. [Dept. Indust. Chem., Banaras Hindu Univ., India.]

Body and visceral fats were obtained from 2 fishes, the rohu (*Labeo rohita*) and the nain (*Cirrhina mrigala*) caught in the River Ganges.

The mixed fatty acids were fractionated by the lead salt and ethanol and lithium salt and acetone methods and the resulting groups of acids of differing mean unsaturation were converted to methyl esters. The esters were then analysed by fractional distillation *in vacuo*.

All the facts contained palmitic acid as the major saturated acid, and the C₁₈ group of unsaturated acids accounted for about 30 per cent. of the total acids of each fat. The rohu fats were noteworthy as fish fats for their relatively high stearic acid content; body fat contained 11.5 per cent. and visceral fat 14.6 per cent. by weight. Unsaturated C₁₆ acids comprised only 8.1 and 8.6 per cent. of the rohu body and visceral fats, but were major components of the fats of the nain, 32.6 and 26.5 per cent., respectively.—G. A. Garton.

BAPTIST, N. G. Determination of essential amino-acids in some Ceylon vegetables. *Brit. J. Nutrition*, 1954, 8, 205-217. [Biochem. Lab., Dept. Physiol., Univ. Ceylon, Colombo.]

Preparations of crude protein from 7 Ceylon vegetables, namely, murunga leaf (*Moringa pterygosperma*), agati leaf (*Sesbania grandiflora*), kankun leaf (*Ipomoea aquatica*), okra (*Hibiscus esculentus*), drumstick bean (*Moringa pterygosperma*), jack seed (*Artocarpus integriflora*) and brinjal (*Solanum melongena*) were obtained by desiccation and subsequent successive exhaustive extractions with ethanol, light petroleum and water. The essential amino-acid contents of the crude proteins were estimated by chemical and microbiological methods; the applicability of the different methods used for the estimation of amino-acids is discussed. The leaf-vegetable proteins were low in methionine, but no marked deficiency of any essential amino-acid was found. Of the "whole" vegetable proteins, jack seed was relatively low in arginine, histidine and methionine and the others in tryptophan, isoleucine and methionine.—G. F. Garton.

DESCHREIDER, A. R. and VAN COILLIE, L. Les traces metalliques dans les legumes frais. [Trace elements in fresh vegetables.] *Lab. Central, Ministère Affaires Econ., Belgium*, Publ. No. 135, pp. 12.

Fe, Zn, Cu, Pb and As were estimated in 3 to 9 samples of potatoes and potato peelings, about a dozen other vegetables which are canned in Belgium, and tomatoes, by methods previously reported by the author (International Agricultural Congress, Rome, 1952). Means and ranges are tabulated from the fresh and dry material with some values from the literature, and the fresh values are also shown graphically.

Values for the different metals tended to run parallel. Spinach contained most Fe, Zn and Cu, followed by chervil. Chervil, endive and chicory contained most Pb, and endive and tomatoes most As.

Since the amounts of trace metals, notably Zn, in fresh vegetables may exceed the limits prescribed in certain countries for canned vegetables, a plea is made for revision of these limits on an international basis.—W. M. Deans.

SORTEBERG, A. Fortsatte forsøk med molybden. [Continued experiments with molybdenum.] *Forskning og Forsøk Landbruget*, 1954, 5, 161-198. [Inst. Jordkultur., Norges Landbruks-høgsk.]

Peat soils from West Norway were found in pot experiments to be deficient in Mo. With lettuce, heavy watering or addition of lime reduced the requirement for added Mo. On a soil with little lime and pH 4.1 to 5.0, Mo deficiency was most severe in timothy, red clover, carrot, parsley, cauliflower and beetroot, and less severe in swedes and radish; oats, barley and alfalfa showed no sign of deficiency, though at pH 4.3 barley gave a better yield when Mo was supplied. On several soils lime was as efficient as Mo in preventing deficiency disease in the plants. Mo deficiency is widespread in Norwegian peat soils.—D. Duncan.

PENCE, J. W., WEINSTEIN, N. E. and MECHAM, D. K. The albumin and globulin contents of wheat flour and their relationship to protein quality. *Cereal Chem.*, 1954, 31, 303-311. [W. Utilisation Res. Branch, Agric. Res. Serv., U.S. Dept. Agric., Albany, Calif.]

The mean albumin and globulin contents of 32 unbleached flours of widely varying type and baking quality were, respectively, 9.1 and 8.3 per cent. of the total flour protein. Both, as well as their ratio, varied significantly among the flours. The albumin and globulin contents also increased directly with total flour protein, but this relationship became inverse when they were expressed as percentages of total protein. The coefficient of regression of loaf volume on flour protein was used to estimate the baking quality of the protein of each flour, although for several of the flours there was difficulty in estimating statistically reliable coefficients. The different levels of protein required in the estimation were obtained by fortifying each flour with its own gluten and water-soluble substances and diluting it with its own starch. Neither the amount of albumin or globulin nor the ratio of albumin and globulin to gluten was correlated significantly with protein quality as measured by the regression lines. The albumin:globulin ratio, however, was correlated with protein quality beyond the 1 per cent. point of significance. Although the total protein content of the flour was also correlated very significantly with protein quality, the partial correlation of albumin:globulin ratio with protein quality, obtained by keeping flour protein constant, retained a high degree of significance.—G. F. Garton.

Fruits

287

RENTSCHLER, H. and TANNER, H. Über die Zusammensetzung der Fruchtsäuren von schweizerischen Obstsorten. 1. Die Fruchtsäuren der schweizerischen Mostbirnensäfte. [Composition of organic acids of Swiss fruit juices. 1. Organic acids of Swiss perry.] *Mitt. Geb. Lebensmittel. Hyg.*, 1954, 45, 42–158. [Eidg. Versuchsanst., Wädenswil.] French and English summaries.

Organic acids in the pressed fermented juice of 12 kinds of Swiss pears were detected by paper chromatography after removal of interfering inorganic acids by ion exchange resins; the methods, which are described in detail, were based on those of Stark *et al.* (Abst. 1341, Vol. 21). As well as malic acid, citric acid was generally present in considerable quantity; this possibly explains the frequent occurrence of "diseases" of perry, especially among peasant producers. Quinic acid, not previously reported as a constituent, was present in amounts of about 0.5 g. per litre; glycolic acid only in small amounts, less than 0.2 g. per litre. Galacturonic acid, ascorbic acid and protocatechuic acid were not found.—W. M. Deans.

Other Types

289

ADRIAENS, E. L. and BIGWOOD, E. J. Contribution à l'étude de la composition en acides aminés de la matière protéique de la graine de coton. [Amino-acid composition of the protein of cottonseed.] *Bull. Soc. Chim. biol.*, 1954, 36, 579–583. [Lab. Biochem., Fac. Méd., Univ. Brussels.]

Examination of cottonseed residues on ion exchange columns showed a protein content of 48.4 per cent. by weight, in agreement with Kjeldahl estimations. The 8 essential amino-acids formed 32.1 per cent. of the protein, which compares favourably with other foodstuffs, but the methionine and cysteine contents were low (0.08 per cent. S). The mechanical and heat treatment used in preparation of the residues was considered possibly to have destroyed part of the sulphur amino-acids.—A. Hepburn.

BELL, J. M., McLAREN, P. D. and McKAY, G. Mineral and protein content of forage crops in central Saskatchewan. *Canad. J. Agric. Sci.*, 1954, 34, 252-260. [Dept. Animal Husb., Univ. Saskatchewan, Saskatoon.]

Data are given for protein, ash, Ca, P, Mg, K, Na and Mn in cultivated grasses, cultivated legumes, native upland grasses, native lowland grasses and hedges, and grasses and legumes grown on alkaline soils. The results are discussed in relation to the nutrient requirements of cattle. It is suggested that the grass hays require supplements of protein, Ca, P and salt.—J. S. Thomson.

MILLS, C. F. Copper complexes in grassland herbage. *Biochem. J.*, 1954, 57, 603-610. [Dept. Phys. Sci., Wye Coll. (Univ. London), Ashford, Kent.]

The object of the work, part of a thesis (Univ. London, 1951), was to investigate the possibility that the copper in herbage from regions where swayback occurs may be present as stable organic complexes which are not available to the animal. Samples of herbage from a Derbyshire farm where swayback regularly occurs and from an unaffected farm in Kent were compared. The results are tabulated of serial extraction with several organic solvents of increasing dielectric constant and finally with water, and of dialysis after extraction with water or a dilute solution of glycine or tartaric acid. Cu was estimated colorimetrically

as diethyldithiocarbamate by an adaptation of the method of Eden and Green (Abst. 2322, Vol. 10). Aqueous extracts of some samples were also chromatographed on paper with phenol-water as solvent in order to separate free cupric ions from copper complexes.

On the average, about two-thirds of the total Cu was insoluble in organic solvents or water. The differences between normal and affected herbage were not great; the latter contained rather less water-soluble Cu. The dialysis experiments revealed seasonal variations in the solubility of herbage Cu, more marked in the normal samples. Chromatography indicated the presence of at least 8 water-soluble copper complexes in normal herbage, as against 5 in affected herbage.

The question now is whether the lower content of water-soluble Cu in affected herbage is sufficient to produce Cu deficiency in the sheep. This demands further information on the availability of water-soluble copper complexes to the ruminant, and studies of this are in progress.—W. M. Deans.

MACINTYRE, W. H., HARDIN, L. J. and HARDISON, M. Fluorine acquired by forage cultures in outdoor and washed atmospheres at Columbia, Tenn. *J. Agric. Food Chem.*, 1954, 2, 832-835. [Univ. Tennessee, Agric. Exp. Stat., Knoxville.]

Six-week-old cultures of red clover and of ryegrass were divided into 2 main groups; one was retained at Knoxville where the plants were grown out of doors or in a greenhouse, the other was sent to Columbia, where the F content of the atmosphere was known to be higher than at Knoxville, and where the plants were grown out of doors or in a chamber in an atmosphere freed from F. Similar experiments were made with Sudan grass grown outside at Knoxville for 6 weeks or for 3 weeks at Knoxville followed by 3 weeks outside or in the chamber at Columbia.

During their growth out of doors at Columbia all plants, in comparison with those at Knoxville, gained F, but those in the treated atmosphere did not do so. Not all the increase at Columbia can be attributed to the plants' having breathed in an atmosphere richer in F; some of the increase may have been due to contamination by dust with a high F content.—D. Harvey.

BINGER, H. P., SULLIVAN, J. T. and JENSEN, C. O. Forage crop constituents. The isolation and analysis of hemicelluloses from orchard grass. *J. Agric. Food Chem.*, 1954, 2, 696-700. [U.S. Reg. Pasture Res. Lab., State College, Pa.]

Holocellulose was prepared from orchard grass (*Dactylis glomerata*) by successive extraction with ethanol-benzene, ammonium oxalate and sodium chlorite. The holocellulose was then extracted with hot water, 0.5 per cent. potassium hydroxide and 1.5 per cent. potassium hydroxide and the hemicelluloses were obtained from these extracts as precipitates upon acidification (pH 3), addition of alcohol, and finally dialysis against running water and evaporation of the alcoholic solution. The hemicellulose precipitates were hydrolysed to yield reducing sugars which were separated by paper chromatography and estimated by electron reflection densitometry.

Xylose, glucose, arabinose, galactose and uronic acids were found in almost all hemicellulose fractions, xylose and glucose giving from 60 to 95 per cent. of the carbohydrates. About 73 per cent. of the hemicelluloses obtained resulted from the water extraction of the holocellulose, the total yield of polyuronide hemicellulose on an ash-, moisture-, and protein-free basis being 12.8 per cent. of the weight of the original grass.

DENT, J. W. and ZALESKI, A. Leafiness and chemical composition of some lucerne strains. *J. Brit. Grassland Soc.*, 1954, 9, 131-140. [Nat. Inst. Agric. Botany, Cambridge.]

Nine strains of lucerne were studied in 2 successive seasons for leafiness, calculated as the ratio of leaf to stem by green weight, at the stage when about 20 per cent. of the flowers were open. Dry matter and chemical composition of leaf and stem were then estimated.

Calculated on green weights the later flowering varieties had a higher leaf:stem ratio than the earlier varieties. The early varieties contained a higher proportion of dry matter in the leaf and a lower proportion of dry matter in the stem than the later varieties. This largely counterbalances the apparently low leaf:stem ratio, and calculated as dry matter the actual leaf:stem ratio was fairly consistent for all varieties.

Chemical analyses for proximate nutrients showed few consistent varietal differences. Crude fibre showed a tendency to increase in the later-maturing varieties at the expense of N-free extractives.—D. M. Walker.

303

ELY, R. E. and MOORE, L. A. Yields of holocellulose prepared from various forages by acid

chlorite treatment. *J. Agric. Food Chem.*, 1954, 2, 826-829. [Dairy Husb. Res. Branch, U.S. Dept. Agric., Beltsville, Md.]

Seven hays, 2 silages and 1 straw were used in experiments comparing the yields of holocellulose prepared by acid chlorite treatment of an "extractive-free" material. Theoretical holocellulose was used as the standard for comparison:

Theoretical holocellulose

$$= 100 - (\text{ash} + \text{protein} + \text{lignin}).$$

Two treatments with acid chlorite gave recoveries ranging from 97 to 103 per cent. of the theoretical holocellulose. Further treatments resulted in apparent losses of carbohydrate.

Lignin by the method of Ellis *et al.* (Abst. 2495, Vol. 16) and N content were estimated on the crude holocellulose and compared with the lignin and N content of the starting material. The holocellulose fraction represented from 66 to 81 per cent. of the dry matter of the "extractive-free" forages studied.—D. M. Walker.

304

KEMBLE, A. R. and MACPHERSON, H. T. Liberation of amino acids in perennial rye grass during wilting. *Biochem. J.*, 1954, 58, 46-49. [Chem. Dept., King's Bldgs., Univ. Edinburgh.]

Samples of young perennial ryegrass were allowed to wilt and were analysed for soluble N, volatile bases, total amide, glutamine, α -carboxyl-N, peptide and monoamino-monocarboxylic acids after 1, 2, 3, 5 and 8 days. Two samples of mature grass were similarly allowed to wilt, one in the presence of water vapour.

The liberation of α -amino-acids lagged behind the increase in soluble N for the first 2 days and most individual acids in fresh grass were in smaller quantities than would have been expected from a uniform breakdown of protein. The free amino-acids were evidently formed by way of peptides, as was confirmed by a sharp rise in the peptide content after 1 day. The concentration of amide reached a maximum after 3 days, when N metabolism ceased and the moisture content had fallen to about 40 per cent.

Proline alone was present in wilting grass in a concentration greater than that expected. After 8 days proline was 50 per cent. in excess of that in the original protein. Wilting mature grass did not synthesise proline under moist conditions, but the amount present was comparable with the amount of amide synthesised. Desiccation possibly alters the normal building-up of amide to proline and the disappearance of amino-acids is the same when moist or dry, which suggests a relation between proline and amide synthesis.

A. Hepburn.

305

KEMBLE, A. R. and MACPHERSON, H. T. Monamino monocarboxylic acid content of preparations of herbage protein. *Biochem. J.*, 1954, 58, 44-46. [Dept. Chem., King's Bldgs., Univ. Edinburgh.]

Protein samples from clover, young lawn grass, mixed grass from permanent pasture, young and old perennial ryegrass, wilted lawn grass and protein from perennial ryegrass treated to simulate silage making were analysed for monoamino-monocarboxylic acids, except methionine.

No significant difference was found in the amino acid composition of the protein from the different fresh herbage or the wilted grass. The protein from ensiled ryegrass had slightly less serine and threonine.—A. Hepburn.

306

POPE, G. S. and WRIGHT, H. G. Oestrogenic isoflavones in red clover and subterranean clover. *Chem. and Indust.*, 1954, No. 33, 1019-1020. [Nat. Inst. Res. Dairying, Univ. Reading, Shinfield.]

The presence of genistein, already reported in subterranean clover (see Abst. 268, Vol. 22) has been confirmed in red clover and that of biochanin A, already found in red clover (Abst. 2165, Vol. 24), has been confirmed in subterranean clover. The colours of the complexes formed by these with methanolic ferric chloride were found to depend on pH, being green in acid and red in alkaline solution.

D. Harvey.

307

WATKIN, B. R. The animal factor and levels of nitrogen. *J. Brit. Grassland Soc.*, 1954, 9, 35-46. [Wye Coll., near Ashford, Kent.]

A study was made of the effects on pasture production of 3 different rates of application of nitrogenous fertiliser (Nitro-chalk) and of grazing by wethers suitably harnessed so as to allow fertilisation also by dung and/or urine. In addition the botanical composition of the sward was examined.

The Nitro-chalk produced a considerable change in the flora by, at the highest rate, causing almost complete disappearance of clover. The increase in production of dry matter per acre was greatest when urine was applied with N, but the additional effect of dung was small. There was evidence, however, that dung stimulated growth of clover when no N or the lowest rate was used. Without N the effect of urine alone was small.

For the effects on the composition of the pasture only data for the no-nitrogen and the highest rate were considered.

The additional effect of excreta on N yield was greatest when urine was returned. With dung alone and no N there was also an effect due pre-

sumably to the stimulation by it of clover growth. At the high level of N dung had no additional effect. In all circumstances yields of K and Mg were increased by the use of N fertiliser.

The earthworm population was influenced more by the application of dung than of urine or N fertiliser.—J. L. Corbett.

308

HARSHBARGER, K. E., NEVENS, W. B., TOUCHBERRY, R., W., LANG, A. L. and DUNGAN, G. H. The yield and protein content of silage corn as influenced by fertilization. *J. Dairy Sci.*, 1954, 37, 976-981. [Dept. Agronom., Univ. Illinois, Urbana.]

Experiments over a 5-year period showed that, in the production of maize for silage, when soils were deficient in plant nutrients the application of commercial fertilisers increased the yield of fresh and dry matter, representing an increase in both ear and leaf stalk material, had little effect on the protein content of the grain, but considerably increased the protein content of the leaf stalk.

J. S. Thomson.

SUTOH, H. [Biochemical studies on silage. 8. On the comparison of digestibility and yield between green forage and silage. 9. On making silage of some wild plants and waste farm products.]

SUTOH, H. and KOMAKI, T. [10. On the effect of supersonic wave to silage-making.]

SUTOH, H. [11. On the evaluation of quality (1).] *Bull. Educat. Res. Inst., Univ. Kagoshima*, 1953, 5, 146-151; 152-158; 159-165; 166-172. [Lab. Nutrit., Fac. Educat., Univ. Kagoshima, Japan.] English summaries.

8. The feeding value of sweet potato vines as green forage or as silage with or without the addition of formic acid was estimated. On an air-dried basis the vines contained protein 8.65, fat 3.04, N-free extract 44.5, fibre 17.5, and ash 14.3 per cent.

The silage made with acid was superior to the control silage, loss of crude protein being 7 and 20 per cent., respectively, and loss of organic matter 7 and 22 per cent.

Trials with guineapigs gave digestibility coefficients generally lower for the silage than for the forage, and lower for the control silage than for the formic acid silage. Total digestible nutrient content of the formic acid and control silage was 92 and 65 per cent., respectively, of that of the forage.

9. Satisfactory silage was made from white clover, green oats, pea vines, onion leaves and Tokoimo-nuka (sweet potato with rice bran) but not from *Solidago serotina*.

Vol. 25, No. 1

10. The use of supersonic waves was not particularly effective in the preparation of silage.

11. A negative correlation ($r = -0.724$) was found between pH and lactic acid content of silage. Above pH 4.2 there was considerable production of butyric acid.—J. S. Thomson.

RICHARD, C. and VIALARD-GOUDOU, A. Le fluor dans les eaux du Sud-Vietnam et des Plateaux Montagnards du Sud. [Fluorine in the water of southern Viet-Nam and the mountainous plateaux of the south.] *Bull. Soc. Chim. biol.*, 1954, 36, 901-903. [Lab. Contrôle des Eaux, Inst. Pasteur, Saigon.]

The F contents, estimated by a standard method, of 30 waters in Viet-Nam are tabulated. Apart from brackish wells they were generally low; the mean for 11 surface waters was 0.137 and for 8 deep wells 0.074 mg. F per litre.—W. M. Deans.

312

MITCHELL, T. J., DONALD, E. M. and KELSO, J. R. M. An examination of Scottish heather honey. *Analyst*, 1954, 79, 435-442. [Tech. Chem. Dept., Royal Tech. Coll., Glasgow.]

Forty-two samples, 30 of which were predominantly of ling honey, were collected from widely separated districts and, by methods which are detailed, were examined for colloid, nitrogen and ash and for pH and free acidity. With standard equipment as described the thixotropic ratio was obtained from the times required for a steel ball to fall through 14 cm. of honey after it had stood for 24 hr. and after it had been stirred vigorously.

Arrangement of the samples in ascending order of pH showed that with it ash and colloid contents tended also to increase and there was some evidence, less definite, that N content and thixotropic ratio increased with increasing colloid content. Bell heather and clover honey with ratios generally below 3 did not exhibit thixotropy; for ling honey the ratio sometimes exceeded 100.—D. Harvey.

The effect was investigated of deficiency of vitamin A or D or members of the B vitamin complex on the formation of antibodies in the rat. Lack of any vitamin except vitamin D and vitamin B₁₂ impaired antibody formation in response to Rh-negative human erythrocytes. Vitamin deficiencies had no apparent effect on total lytic serum complement. There was no relation between the number of circulating lymphocytes and the ability of vitamin-deficient rats to produce antibodies. No change in the electrophoretic pattern of serum protein in immunised and nonimmunised rats could be related to vitamin deficiencies.

REISS, R., PISARZEWSKI, A., GRAFFI, A. and HEBEKER, W. **Über chemische Frühveränderungen.** *N.A. and R.*, January 1955

erungen der Rattenleber nach Verfütterung cancerogener Azofarbstoffe. 7. Veränderung des Vitamin B₁-, B₂- und C-Gehaltes. [Early chemical changes in the rat liver after administration of carcinogenic azo dyes. 7. Changes in the content of vitamin B₁, B₂ and C.] *Arch. Geschweulstforsch.*, 1954, 7, 120-126. [Inst. Med. Biol., Berlin-Buch.]

After a preliminary period of 4 weeks on a normal diet rats were given 20 mg. of 3-methyl-4-dimethylaminobenzene daily for 4 days with a diet of low vitamin content. They were then killed and the vitamin content of the liver was estimated. The administration of the carcinogen caused an increase of vitamin B₁ and vitamin C, and a decrease of riboflavin, calculated on fresh weight and on nitrogen content. There was no apparent sex difference. Substitution of the low-vitamin diet for the normal diet in the 4 weeks of

preparation did not alter the effect of the carcinogen on the vitamin content of the liver.

SAVCHIK, A. P. Spetsificheskoe proyavleniye gipovitaminozov i zashchitnye svoystva nepigmentirobannoi kozhi u sel'skokhozyastvennykh zhivotnykh za polyar'ya. [Specific vitamin deficiency and the protective qualities of unpigmented skin of farm animals in the Arctic Circle.] *Veterinariya*, 1954, 31, No. 2, 53-55. [Vet. Bacteriol. Lab., Vorkuta.]

The low vitamin content of fodder in areas within the Arctic Circle is reported as the cause in farm animals of various types of vitamin deficiency [not specifically described]. Observations on cattle, horses and pigs suggested that those of light colour were affected to a less extent than those with pigmented skins.—H. Scherbatoff.

VITAMIN A

326

AMES, S. R., RISLEY, H. A. and HARRIS, P. L. Simplified procedure for extraction and determination of vitamin A in liver. *Anal. Chem.*, 1954, 26, 1378-1381. [Res. Labs., Distillation Products Industries, Div. Eastman Kodak Co., Rochester, N.Y.]

A portion of liver weighing from 3 to 5 g. was ground in a mortar with from 3 to 5 times its weight of anhydrous sodium sulphate until completely dry. The dry powdered liver was shaken with 100 ml. ether for 2 min. and after the solids had separated a portion was taken, the ether was removed and the residue was taken up in 1 ml. chloroform. Two drops of acetic acid were added and then 10 ml. of a saturated solution of SbCl₃ in chloroform, and the resulting blue colour was measured at wavelength 620 mμ. in a colorimeter. A standard curve of reference was used prepared from standard vitamin A. For livers that contained less than from 5 to 10 μg. vitamin A per g. the procedure was not suitable on account of the turbidity produced in the cell by large amounts of ether-soluble material. The average recovery of 30, 150 or 300 μg. added vitamin A was 98.6 per cent. The method compared favourably with four other published methods.—R. J. Ward.

327

GREEN, J. and SINGLETON, D. O. A rapid chromatographic method for the determination of vitamin A in whale-liver oils. *Analyst*, 1954, 79, 431-434. [Walton Oaks Exp. Stat., Vitamins, Ltd., Tadworth, Surrey.]

Vol. 25, No. 1

A column of neutralised floridin earth was used to remove substances which cause irrelevant absorption during the spectrophotometric estimation of vitamin A in whale liver oils. Oils free from anhydrovitamin A were dissolved in *n*-hexane and passed through a column which had been neutralised with ammonia vapour and washed with *n*-hexane. The vitamin A esters were eluted with further quantities of *n*-hexane. If anhydrovitamin A was present, the oil was first saponified and then passed through a column which had been neutralised with ethanolic ammonium hydroxide and washed with *n*-hexane. The vitamin A alcohol was eluted with a mixture of 80 per cent. benzene and 20 per cent. *n*-hexane. The absorption curves obtained were in good agreement with those published for vitamin A between 300 and 350 mμ.—R. J. Ward.

328

WAGNER, K. H., LINDEN, G. and STUMPF, A. Photometrische Untersuchungen des zeitlichen Extinktionsabfalles des Vitamin A-Metallhalogenid-Farbkomplexes. [Photometric studies of the decrease with time of the extinction of the vitamin A metal-halogen colour complex.] *Hoppe-Seyler's Ztschr.*, 1954, 296, 193-204. [Inst. Ernährungswiss., Med. Akad., Justus-Liebig-Hochsch., Giessen.]

The rate of fading of the blue colour produced by vitamin A with SbCl₃ was studied by measuring the absorption at 610 mμ. in a photo-electric spectrophotometer. The colour produced by the standard vitamin A acetate fell to half its value in

430 sec. For practical purposes the fall which occurred between the addition of the reagent and the routine measurement 20 sec. later was small enough to be neglected. The addition of substances interfering with the development of colour, such as dichloroethylene, lowered the curve of fading at all its points. It was not possible, therefore, to extrapolate back to a point which would have been given in the absence of the interfering substances. The observations confirmed that the SbCl_3 method is reliable for estimating vitamin A in preparations that have been purified by chromatography, but that the results are unreliable when the source of vitamin contains interfering substances.—T. Moore.

BALAKHOVSKII, S. D., SHARTZ, S. E., and DROZDOVA, N. N. K voprosu o fiziologicheskoi deistvii analoga bokovoi tzepe vitamina A 2,6-dimetiloktatriena (allootzimen). [Physiological action of the side-chain analogue of vitamin A, 2: 6-dimethyloctatriene (alloocimene).] *Dokl. Akad. Nauk S.S.S.R.*, 1953, **92**, 377-379. [Mosk. Glaz. Klin. Bol'n.]

It is stated to have been shown that carotene and other substances analogous to vitamin A can alleviate painful irritation without disturbing pain sensitivity or conduction along nerve fibres. Experiments with *alloocimene* on isolated segments of guinea-pig intestine showed that, in common with other substances of the group, it possessed a high degree of antihistamine activity. On administration to normal subjects and to patients with painful disorders of the eye corneal sensitivity was increased, but there was a definite analgesic action, with diminution in the manifestations of eye irritation such as muscle spasm, photophobia and lachrymation with obstruction of the lachrymal duct.—D. W. Taylor.

332

BICKOFF, E. M., LIVINGSTON, A. L. and BAILEY, G. F. Evaluation of two methods for the determination of carotene. *J. Assoc. Off. Agric. Chem.*, 1954, **37**, 509-518. [W. Utilisation Res. Branch, Agric. Res. Serv., Albany 6, Calif.]

Possible sources of error in the A.O.A.C. method for estimating carotene were reviewed and some of them evaluated. The possibility exists of isomerisation through heat, and of oxidation, during the extraction. Extraction of carotene is never complete, and about 4 per cent. more can be extracted by subsidiary procedures. There are possibilities of variation at the stage of chromatography; for instance, with standard volumes of eluent the carotene is not all eluted, and with large volumes non-carotene pigments are eluted.

The modified A.O.A.C. method now in use at the Western Region Research Laboratory was compared with the standard A.O.A.C. method. The carotene values obtained with the former were 5 per cent. higher than with the latter, which was due to a combination of causes, the most important being better control in elution of the carotene from the magnesia.—V. H. Booth.

333

BOOTH, V. H. Carotene: effect of antioxidant on its determination. *Analyst*, 1954, **79**, 507-509. [Dunn Nutrit. Lab., Univ. Cambridge.]

Dried grass and lucerne meals were treated with NN' -diphenyl- p -phenylenediamine, an anti-oxidant sometimes used to prevent loss of carotene on storage at concentrations ranging from 100 to 2000 p.p.m. The carotene content of the material was estimated before and after treatment with the anti-oxidant by extraction with light petroleum, b.p. 80° to 100°C , and chromatographic separation on alumina. The mean ratio of the carotene content of the treated to that of the untreated meal was 1.003. When defatted bonemeal was used for the chromatogram, the mean ratio was 1.03. The present method eliminated the interference of NN' -diphenyl- p -phenylenediamine in the estimation of carotene which was reported by Beauchene *et al.* (Abst. 4123, Vol. 23).—R. J. Ward.

Technique de préparation des extraits actifs. [Antixerophthalmic activity of the carotenoid pigment of prawns (*Aristeomorpha foliacea*, Risso and *Aristeus antennatus*, Risso). Technique for preparing active extracts.] *C.R. Soc. Biol.*, 1954, **148**, 533-536.

N.A. and R., January 1955

Results obtained previously with *A. foliaceae* were confirmed (Absts. 2951, Vol. 18; 3318, Vol. 19; 282, Vol. 20).

Chromatography on alumina enabled astaxanthin to be obtained from the hepatopancreas and other tissues of the prawn *Aristeus antennatus*. Complete separation of astaxanthin was possible even when small amounts of carotene and vitamin A had been added. Xerophthalmia in the rat was cured by astaxanthin, the effect of which cannot, therefore, be explained by the presence of carotene or vitamin A as an impurity.

ZALOKAR, M. Studies on biosynthesis of carotenoids in *Neurospora crassa*. *Arch. Biochem. Biophys.*, 1954, 50, 71-80. [Nat. Inst. Arthritis Metabol. Dis., Nat. Inst. Health, Bethesda, Md.]

Two wild types of the fungus *Neurospora crassa* were crossed and after the spores had been isolated the strain with the best production of conidia and of carotenoid colour was selected for investigation. Most of the colour is concentrated in the conidia and conidia-bearing hyphae, so it was necessary for assessment of pigment production to control the proportion of conidia to mycelium. Production of conidia was suppressed when necessary by the use of submerged cultures, for which polyoxyethylene sorbitan monooleate was added to the medium to keep the hyphae wet. The pigments were extracted with methanol and acetone, and were separated by chromatography.

When grown in the dark, the mycelium remained almost colourless. Pigment production began on exposure to oxygen and light, the rate increasing rapidly during the first hour and then falling off; after 24 hr. there was no further production of pigment except when conidia were formed or when fresh medium was added, allowing new growth. The independent appearance of the different carotenoids produced after exposure to light and oxygen did not indicate a sequence in biosynthesis, but phytoene, which was present before exposure to air and light, and disappeared with the appearance of acidic pigment, might be a precursor. In mycelia exposed to air there was more phytoene and less acidic pigment; in mycelia exposed to oxygen more acidic pigment and correspondingly less phytoene were found. In mycelia free of

conidia only the young hyphae on the surface produced carotenoids; those in the lower layers remained colourless. The conidia and the hyphae bearing them produced much larger quantities of the pigments than the mycelium itself and in different proportions. No increase in pigment production occurred when substances were tested in the culture medium as possible precursors of the carotenoids.—I. M. Sharman.

CURL, A. L. and BAILEY, G. F. Orange carotenoids. Polyoxigen carotenoids of Valencia orange juice. *J. Agric. Food Chem.*, 1954, 2, 685-690. [W. Utilisation Res. Branch, Agric. Res. Serv., U.S. Dept. Agric., Albany 6, Calif.]

The unsaponifiable fraction of a light petroleum extract of Valencia orange juice was separated by countercurrent distribution in a Craig apparatus into 6 fractions. Of the total carotenoids the several fractions had the following approximate percentages: hydrocarbons 6, monols 13, diols 22, mono-ether diols 26, di-ether diols 23, mono-ether polyols 10. The present paper is concerned with the analysis of the last 3 fractions totalling 60 per cent. of the carotenoids. Each fraction was chromatographed on magnesium oxide and developed with ethanol or benzene in light petroleum. Seventeen pigments were thus separated. The spectral absorption curve for each was recorded from 290 to 550 m μ . Each pigment was treated with HCl in ether to determine the number of cyclic ether groups in the molecule.

By study of the absorption curves including *cis* peaks, chromatographic behaviour including the results of mixed chromatograms, and chemical reactions, some of the pigments were identified. Five were probably antheraxanthin, mutatoxanthin, violaxanthin, auroxanthin and zeaxanthin-epoxide-furanoxide. Two others were tentatively identified as trollixanthin and trollichrome. Three have probably not been hitherto described and they have been named. The 7 others were stereoisomers of these 10. All 17 were apparently epoxides or furanoxides of xanthophylls. The

possibility is discussed that some may have been formed during the manipulations.—V. H. Booth.

GEBAUER, H. Die Milz der Albinoratte bei Vitamin A-Mangel. [The spleen of the albino rat in vitamin A deficiency.] *Naturwissenschaften*, 1954, 41, 288-289. [Anst. Vitaminforsch., Potsdam-Rehbrücke.]

In 40 per cent. of rats deprived of vitamin A the spleen was found to be reduced to about one-third of the normal weight for animals of a given size. Microscopic studies indicated reduction of the spleen pulp and increase of the fibrous parts of the organ. It is suggested that the spleen may play an important part in resistance to infections, and that the widely different lesions seen in vitamin A deficiency may have a common origin, being secondary to damage in the spleen.

PIERANGELI, E. and RADICE, J. C. Absorción de la vitamina A en roedores y batracios. Microscopia fluorescente. [Absorption of vitamin A in rodents and batrachians. Fluorescent microscopy.] *Rev. Asoc. argent. Dietologia*, 1953, 11, 77-82.

Vitamin A in oil is unstable to ultraviolet light and its fluorescence disappears in a very short time. The fluorescence can be seen in a drop on a slide or in sections of tissues, such as the liver and adrenal gland, which are loaded with vitamin A. The fluorescence was used to follow the absorption of vitamin A in rodents and batrachians by means of the fluorescence microscope. Rats deprived of vitamin A showed no fluorescence in the liver or adrenal glands, and when deprived rats were given large doses of vitamin A at varying intervals before being killed, the progress of absorption could be followed until, after from 3 to 5 hr., the Kupffer cells were loaded with the vitamin, and after from 5 to 7 hr. the trabeculae. Normal rats loaded with vitamin A showed a similar phenomenon. In rats absorption is mainly from the jejunum and ileum. In batrachians it is from the gastric region and small intestine, and the liver shows Kupffer cells loaded with vitamin A.

DZIEWIATKOWSKI, D. D. Vitamin A and endochondral ossification in the rat as indicated by the use of sulfur-35 and phosphorus-32. *J. Exp. Med.*, 1954, 100, 11-24. [Hosp. Rockefeller Inst. Med. Res.]

Experiments were made with young albino rats which were given single intraperitoneal injections of sodium sulphate made with ³⁵S or of disodium phosphate made with ³²P. The metabolism of the sulphur was studied by measuring the radioactivity of the bones and of isolated chondroitin sulphate during the next 24 to 120 hr., and by taking radio-autographs of the bones. One group of non-deprived rats was studied at weaning; the remainder were given a diet deficient in vitamin A, usually for 6 weeks. Some of them were given an intraperitoneal injection of 2 mg. vitamin A dissolved in ethyl laurate immediately before the sulphate, others were injected only with ethyl laurate. In rats which had not been depleted of vitamin A injection of the vitamin had no effect on the metabolism of sulphate. In deficient animals injection of vitamin A decreased the concentration of inorganic sulphate S in the blood serum from 2.5 mg. per cent. to 1.8 mg., which is close to the normal value of 2.0 mg. for rats of the same age. The uptake of sulphate and phosphate by the femur and tibia was reduced in rats depleted of vitamin A, and was increased by injection of the vitamin.

Radio-autography showed that sulphate was increased in the epiphyseal cartilage; phosphate was increased in the diaphysis immediately adjacent to the epiphyseal cartilage plate. The amount of specific radio-activity of sulphate from chondroitin sulphate isolated from the skeletons of rats

N.A. and L., January 1955

deficient in vitamin A fell progressively as the deficiency advanced. After injection of vitamin A the radio-activity rose to equal or exceed the normal. Injection of vitamin A increased the radio-activity also of the sulphate of sulphomucopolysaccharides isolated from the skin.

FELL, H. B., MELLANBY, E. and PELC, S. R.
Influence of excess vitamin A on the sulphate metabolism of chick ectoderm grown in vitro.
Brit. Med. J., 1954, ii, 611. [Strangeways Res. Lab., Cambridge.]

Radio-autographs were made from sections of chick ectoderm which had been grown *in vitro* in a medium of plasma and embryo extract in the ratio 3:1, containing radio-active sulphur as sodium sulphate. The squamous, keratinising epithelium which was formed gave only a faint radio-autograph. The addition of a high concentration of vitamin A alcohol to the medium caused a dense radio-autograph in the region where epithelium of the mucus-secreting type (see Abstr. 4147, Vol. 23) had grown instead of squamous epithelium. Proof was, therefore, obtained of the effect of excess vitamin A in increasing the metabolism of sulphur in the epithelium to a value comparable with that occurring in normal mucus membrane.—T. Moore.

346

COHLAN, S. Q. **Congenital anomalies in the rat produced by excessive intake of vitamin A during pregnancy.** *Pediatrics*, 1954, 13, 556-567. [Dept. Paediat., Beth Israel Hosp., New York.] Spanish summary.

Female rats were kept on a diet of proprietary pellets and were mated for one night when in the pre-oestrous state. Some of them were given massive doses of an aqueous dispersion of vitamin A for varying periods during pregnancy. Others received the dispersing agent without the vitamin. Usually the animals were killed shortly before parturition was expected. From 100 controls untreated with vitamin A 84 litters were obtained with 831 normal offspring. From 210 females given 35,000 I.U. vitamin A from the 2nd, 3rd or 4th to the 16th day of gestation only 25 litters were obtained with 148 offspring of which 77 were malformed. The abnormalities observed included protrusion of part or all of the forebrain, malformation of the eyes, cleft palate, shortening of the mandible and maxilla, spina bifida with meningocele, and hydrocephalus. From the 7th to 10th day of gestation was the time of critical susceptibility to the teratogenic effect of vitamin A in excess. Daily doses of 15,000 I.U. vitamin A did not cause foetal malformations.—T. Moore.

LEROY, A. M. and LÉRY, G. **Comparaison de la distribution du facteur vitaminique A sous forme d'axérophthol et sous forme de carotène pour la satisfaction des besoins des volailles. [Distribution of vitamin A as axerophthol or carotene to meet the requirements of fowls.]** *Ann. Zootech.*, 1953, 2, No. 2, 149-157. [Lab. Recherches Zootech., Inst. Nat. Agronom., Paris.]

In following years two successive batches of hens were used to study the allowance of carotene or vitamin A necessary for survival, laying, and satisfactory hatching of eggs. In the first batch heavy mortality was not prevented by 5000 I.U. of carotene or vitamin A, but a greater number of eggs was laid with vitamin A than with carotene. For the second batch of hens vitamin A was raised to 10,000 I.U. and carotene to 20,000 I.U., and no death occurred. Egg laying was now the same with both supplements. The vitamin A content per egg from hens given carotene and vitamin A, respectively, was 520 and 715 I.U. in the first batch and 608 and 743 I.U. in the second batch. Hatching trials on the second batch gave only 8 and 24 per cent. of eggs hatched from hens given carotene and vitamin A, respectively. When vitamin E as wheat germ was given in addition to the other supplements, the percentage of eggs hatched was raised to 32 and 39, which showed that deficiency of vitamin E could obscure the favourable action of carotene or vitamin A. It is recommended that laying hens weighing about 2 kg. should be allowed at least 360 µg. vitamin A or 1800 µg. carotene per head daily. Vitamin A is best supplied as fish liver oil and vitamin E as wheat germ oil.—T. Moore.

348

CHARLET-LÉRY, G., FRANÇOIS, A. C. and LEROY, A. M. **Effet de l'ingestion de protéines iodées sur la ponte et sur la teneur en vitamine A des œufs de poule. [Effect of iodinated protein on egg production and on the vitamin A content of hen's eggs.]** *Ann. Zootech.*, 1953, 2, No. 2, 159-161. [Lab. Recherches Zootech., Inst. Nat. Agronom., Paris.]

Twenty chickens, aged 6 months, were maintained in an unheated laying battery under observation for a preliminary period of 3 weeks. They were then separated into two equal groups according to bodyweight and rate of growth since hatching. Both groups were given the same diet and one received a supplement of iodinated protein in the form of a commercial product "thyroboline" obtained by the iodination of proteins extracted from thyroid. The supplement containing 1.4 per unit. thyroxine was added at the rate of 15.5 g. per 100 kg. diet. Both groups

were given supplements of vitamins A and D₃. Laying capacity was then recorded, or if they had not begun to lay their exterior characteristics, width of pelvis and depth of abdomen, were measured. No significant difference between the groups in growth rate or in laying capacity was found. Neither was there any appreciable difference in average food consumption. The eggs of those that received iodinated protein were found to contain less carotene and less vitamin A than those from the control birds. The average carotene of the yolks of the eggs obtained from the supplemented group was 66 $\mu\text{g.}$ per 100 g., compared with 104 $\mu\text{g.}$ per 100 g. for the control groups; the vitamin A values were 326 and 416 $\mu\text{g.}$ per 100 g.—I. M. Sharman.

349

CHARLET-LÉRY, G., FRANÇOIS, A. C. and LEROY, A. M. Influence du facteur vitaminique A (axérophthol ou carotène d'huile de palme associé au tocophérol) sur la ponte et les phénomènes de reproduction chez la poule. [Effect of vitamin A (axerophthol or carotene in palm oil associated with tocopherol) on egg laying and phenomena of reproduction in the hen.] *Ann. Zootech.*, 1953, 2, No. 2, 163-176. [Lab. Recherches Zootech., Inst. Nat. Agronom., Paris.]

Hens were given 4030 $\mu\text{g.}$ carotene from red palm oil, or from 1270 to 1350 $\mu\text{g.}$ vitamin A palmitate, per kg. dry mash. Each supplement was supplied with or without from 5580 to 5950 $\mu\text{g. dl-}\alpha\text{-tocopherol}$ per kg. mash, making 4 groups in all. Just before feeding, the vitamins were mixed with oats which were a component of the mash. The birds picked out the oats and ate them quickly, which minimised the loss of vitamin by oxidation. The number of eggs laid from December to July was the same whether vitamin A or carotene was given, but the percentage hatching was better with vitamin A. The tocopherol supplements had no effect. By raising the intake of vitamin A or carotene the concentration in the egg yolk could be increased.—T. Moore.

350

PIERCE, A. W. The effect of intake of carotene on reproduction in sheep. *Austral. J. Agric. Res.*, 1954, 5, 470-483. [Div. Biochem., C.S.I.R.O., Univ. Adelaide, S. Australia.]

Merino ewes aged from 4 to 7 years, presumably with normal reserves of vitamin A, were given a basal diet which supplied about 10 $\mu\text{g.}$ carotene per kg. bodyweight daily. After 16 months the value for vitamin A in the plasma had fallen from an average initial value of 27 $\mu\text{g.}$ per 100 ml. to one of only 13, and most of the sheep were found to be suffering from night blindness. Supplements

of lucerne were then given to supply 50, 100, 150 or 200 $\mu\text{g.}$ carotene per kg. bodyweight daily. Reproduction was considered to be satisfactory with all the supplements. After 34 weeks the content of vitamin A in the blood plasma had risen to about 22, 28, 32 and 37 $\mu\text{g.}$ per 100 ml., respectively, for the 4 supplements.

In a second experiment after 19 months of restriction the average vitamin A value fell from an initial value of 34 $\mu\text{g.}$ per 100 ml. to 21. The sheep were then continued as before, or given lucerne to supply 50, 75 or 100 $\mu\text{g.}$ carotene per kg. bodyweight daily for the first mating, 25, 50, 75 or 100 $\mu\text{g.}$ for the second mating, and none or 25 or 50 $\mu\text{g.}$ for the third mating. Reproduction was normal in all the groups for the first and second matings apart from failures not considered to be due to vitamin A deficiency. From the third mating no viable lamb was born to the group receiving the basal ration only or the supplement of 25 $\mu\text{g.}$ carotene. It was considered that 50 $\mu\text{g.}$ carotene per kg. bodyweight daily was necessary for repeated reproduction in sheep.—R. J. Ward.

351

CHURCH, D. C., MACVICAR, R., BIERI, J. G., BAKER, F. H. and POPE, L. S. Utilization of intravenously-administered carotene by sheep and cattle. *J. Animal Sci.*, 1954, 13, 677-683. [Oklahoma Agric. Exp. Stat., Stillwater.]

Yearling wethers were given a ration low in carotene and a mineral mixture for 8 weeks at the end of which time the blood plasma values for vitamin A ranged from 10 to 28 $\mu\text{g.}$ per 100 ml. Each wether then received an intravenous injection of 9.2 mg. of an aqueous carotene preparation. Blood samples were taken at intervals between 10 min. and 10 days after the injection. The initial average plasma value for carotene in $\mu\text{g.}$ per 100 ml. was 1.4. From a mean value of 612 $\mu\text{g.}$ 10 min. after injection, the value fell rapidly during the first 6 hr. to 52, then decreased steadily until, after 5 days, almost all the carotene had disappeared from the bloodstream. The initial mean plasma value for vitamin A was 21 $\mu\text{g.}$ per 100 ml. Within 1 hr. the value had risen to 34 and it continued to rise until, 9 hr. after injection, the mean value was 48. A steady fall then occurred until, after 10 days, the value was 25. The mean carotene content of the liver 12 days after injection was 3.1 $\mu\text{g.}$ per g. dry matter, compared with 1.8 for similar untreated wethers.

In a similar experiment calves were given a ration without carotene and were injected with from 13.7 to 17 mg. of an aqueous carotene preparation. The initial mean carotene value for the blood plasma was 11.9 $\mu\text{g.}$ per 100 ml. and it rose to 307 $\mu\text{g.}$ 10 min. after the injection. The peak value was followed by a rapid fall to 89 after 2 hr.

N.A. and R., January 1955

and that value was maintained for 24 hr. After 10 days the value was still 32. For vitamin A there was no significant difference between the mean values for samples taken at different times after the injection. Values for vitamin A and carotene in the liver were, respectively, 2.5 and 0.7 $\mu\text{g.}$ per g. dry matter before injection and 3.1 and 2.5 after it.—R. J. Ward.

352

BONADONNA, T. and KAAH, I. Primi risultati della somministrazione di vit. A e di olio di germi di grano ai tori. [First results of the administration of vitamin A and wheat germ oil to bulls.] *Zootec. Vet.*, 1954, 9, 148-158; 172-177; 206-211. [Ist. Sper. Ital. "L. Spallanzani" Fecond. Art., Milan.] English summary.

In the Centro Tori of the Institute, the ration for bulls remained much the same from 1948 onwards; once a month a concentrate containing 500,000 I.U. vitamin A and 125,000 I.U. vitamin D was injected subcutaneously, and vitamin C, 5 to 8 g. daily for from 3 to 5 days, was injected intravenously from time to time. From 13 June 1953 every bull received daily 50 ml. fresh wheat germ oil containing 25 mg. crystalline vitamin A (Roche), with 100 g. wheat germ flour from which the oil had been extracted. No untreated group was maintained but comparison was made between performance between 13 May and 12 October in 1952 and in 1953, and between 13 May and 12 June 1953 and in the pre-experimental period.

The quantity and character of the semen collected were recorded for 12 bulls of different breeds. Detailed protocols are given for each animal, and summary tables 1, 2 and 3 are mentioned in the text but are stated to be supplied only with reprints. It is concluded that treatment with vitamin E was followed by production of a larger amount of semen of better quality and usually of greater vitality. The less efficient bulls seemed to benefit more than the more efficient; from the semen of one bull abnormal spermatozoa, which had previously been present, disappeared entirely. The amount of fructose in the semen increased on treatment.—E. M. Hume.

ROUSSEAU, J. E. (Jr.), EATON, H. D., HELMBOLDT, C. F., JUNGHERR, E. L., ROBRISH, S. A., BEALL, G. and MOORE, L. A. Relative value of carotene from alfalfa and vitamin A from a dry carrier fed at minimum levels to Holstein calves. *J. Dairy Sci.*, 1954, 37, 889-899. [Dept. Animal Indust., Storrs Agric. Exp. Stat., Conn.]

Forty male calves were reared on vitamin-A-deficient rations. At about 220 lb. bodyweight

and about 12 weeks old they were given carotene at one of 5 levels, 12, 18, 24, 30 or 36 $\mu\text{g.}$, or vitamin A at one of 5 levels; 2, 4, 6, 8 or 10 $\mu\text{g.}$, per lb. bodyweight daily. Dried alfalfa meal was used as the source of carotene, and the source of vitamin A was a commercial preparation in a dry carrier. Blood samples were taken, and the heart rate, rectal temperature and cerebrospinal fluid pressure were recorded at intervals. After 16 weeks the calves were slaughtered and tissues were analysed.

The minimum amounts of carotene and vitamin A required to maintain a plasma value of 10 $\mu\text{g.}$ vitamin A per 100 ml. were, respectively, 31 and 3.8 $\mu\text{g.}$ per lb. bodyweight daily. To achieve a liver concentration of 0.6 $\mu\text{g.}$ per g. the corresponding amounts were 30 and 3. To maintain a minimum cerebrospinal fluid pressure of 120 mm. water, measured shortly before slaughter, the amounts were 33 and 6.4. To prevent papillary oedema, the amounts were more than 36 and 8. Prevention of squamous metaplasia in the main duct of the parotid gland required 24 and 6, and prevention of similar lesions in the interlobular ducts of the same gland required 30 and 4. The equivalence in the amounts of carotene and vitamin A needed agreed with the observations of other workers.—V. H. Booth.

354

ROUSSEAU, J. E. (Jr.), HELMBOLDT, C. F., DEMBICZAK, C. M., JUNGHERR, E. L., EATON, H. D. and BEALL, G. Effect of two levels of intake of a vitamin A depletion ration on some blood constituents and deficiency criteria in the dairy calf. *J. Dairy Sci.*, 1954, 37, 857-862. [Dept. Animal Indust., Storrs Agric. Exp. Stat., Conn.]

Groups of 10 calves, 36 days old, were given a ration deficient in vitamin A, with intakes designed to give 7-day rates of increase of 5 lb. and 10 lb. The ration was continued until the value for vitamin A in the plasma had fallen to less than 4 $\mu\text{g.}$ per 100 ml. for 2 consecutive 7-day periods. The calves were then slaughtered. The average number of 7-day periods was the same for both groups. Plasma carotenoids and vitamin A decreased with rates of change, in $\mu\text{g.}$ per 100 ml., per 7-day period of -2.104 and -2.944, and -1.443 and -1.455 for the low- and high-intake groups, respectively. Hb decreased only in the calves of the low-intake group. Whole blood and plasma ascorbic acid were unaffected. The rate of the calves on the high intake was on the average 20 beats per min. faster than of those on the low intake. The incidence of squamous metaplasia in the interlobular ducts of the parotid gland was significantly greater in the high-intake group.—R. J. Ward.

355

WHITE, R. F., EATON, H. D. and PATTON, S. Relationship between fat globule surface area and carotenoid and vitamin A content of milk in successive portions of a milking. *J. Dairy Sci.*, 1954, **37**, 147-155. [Dept. Animal Indust., Storrs Agric. Exp. Stat., Conn.]

Four first-lactation Holstein cows on a pasture of bluegrass and ladino clover were given a grain mixture with 13.4 per cent. crude protein at the rate of 1 lb. to 4 lb. milk produced, and U.S. No. 1 alfalfa hay was given to appetite. They were examined during successive fortnightly periods; samples of milk were collected every third evening for a single quarter and from each quarter of every cow once during the experiment. Specimens of whole and skimmed milk were taken from each sample, and globule size and vitamin A and carotene content were recorded.

Average values for 60 samples showed for carotenoids a higher value, 18.06 $\mu\text{g.}$ per g. fat, in skimmed milk than in whole milk, 9.26 $\mu\text{g.}$ Corresponding values for vitamin A were 9.71 and 7.37 $\mu\text{g.}$ per g. fat. The fat globule surface-to-volume ratio also was higher in the skimmed milk ($2.2935 \mu^{-1}$) than in the whole milk ($1.6494 \mu^{-1}$). The results support the hypothesis that carotenoids and vitamin A are concentrated at the surface of the fat globule. Further examination of the results for whole milk showed that the amounts of both carotenoids and vitamin A per g. fat had significant positive trends with globule surface-to-volume ratios. From the magnitude of the trends, carotenoids and vitamin A were thought not to form continuous surface layers but to exist possibly in dilute solution, or as a loose chemical complex on the globule surface. Calculated values for the concentration of carotenoids and vitamin A at the globule surface would appear to be as high as 2.6×10^{-4} and 1.9×10^{-4} $\mu\text{g.}$ per sq. cm., respectively; corresponding values for the interior of the globule would be only 0.000476 and 0.000381 per cent. by weight.

In confirmation of earlier work the vitamin A per g. fat showed no trend in relation to the stage of milking, though carotenoids showed a highly significant tendency to decline until about the midpoint and then to increase. Globule size, whether expressed as surface-to-volume ratio or as mean diameter, showed no trend with stage of milking, though fat percentage increased significantly, the final percentage being more than twice the initial.

I. M. Sharman.

356

NARAYANAN, K. M., SHROFF, N. B., ANANTAKRISHNAN, C. P. and SEN, K. C. Vitamin A in dairy products. 2. Vitamin A in curd and ghee from fortified milk. *Indian J. Dairy Sci.*, 1954, **7**, 76-82. [Indian Dairy Res. Inst., Bangalore.]

Specimens of cow and buffalo's milk were examined for vitamin A after different treatments. In the first series of experiments 5 specimens each of whole milk, whole milk fortified with oil-soluble vitamin A, and skimmed milk fortified with water-miscible vitamin A, were investigated, half of each specimen being soured for 24 hr. at room temperature. Analysis of the unsoured milk and dahi (soured milk) showed that both forms of vitamin A used for fortification were stable during the process of souring. In further experiments it was found that boiling or keeping fortified milk at 50° F. for 24 hr. did not increase the solubility of water-miscible vitamin A in the milk fat. Thus, with cow's milk, an average vitamin A content of 33.8 I.U. per g. fat was found in the 5 specimens examined without treatment, 33.5 I.U. in the specimens held at 50° F., and 34.1 I.U. in those that had been boiled. During the preparation of ghee from cow's milk fortified with water-miscible vitamin A, 6.6, 6.8 and 60.8 per cent. of the water-miscible form became soluble in cream, creamery and desi ghee, respectively. The last value was obtained when the curd was soured for 1 day; after souring for 3 days the value fell to 60.2. Corresponding values for buffalo milk were 7.3, 7.6, 56.3 and 55.9, respectively. Vitamin A was almost unaffected when ghee was prepared from cream fortified with water-miscible vitamin A, by direct cooking at 115° F.—I. M. Sharman.

NIEMAN, C. De vitamine A-activiteit van verse varkensreuzel. [Vitamin A activity of fresh lard.] *Voeding*, 1954, **15**, 232-240. [Nederland Inst. Volksvoeding, Amsterdam.] English summary.

Fresh lard was tested biologically for its vitamin A potency in comparison with vitamin A acetate. Lard as 30 per cent. of a diet containing casein or gluten with added tryptophan, methionine and lysine, and no other source of vitamin A, supported good growth in rats. It was calculated that the vitamin A potency of the lard was at least 0.7 I.U. per g. An unsaponifiable fraction from lard was shown to have vitamin A activity but its potency was not determined. The results are discussed with reference to those of Herb *et al.* (Abst. 1709, Vol. 24) and of Lowe and Morton (Abst. 1710, Vol. 24).

JONES, L. G., ZSCHELLE, F. P. and GRIFFITH, R. B. Carotene and protein contents of alfalfa as influenced by variety and certain environmental factors. *Hilgardia*, 1953, **22**, 179-202. [Dept. Agronom., California Agric. Exp. Stat., Davis.]

Methods of sampling alfalfa (lucerne) were studied and the advantages and disadvantages of

N.A. and R., January 1955

some are discussed. The method recommended is to take 25 culms from a plot, dry them, analyse sub-samples and base all analyses on dry weight. Loss of dry matter in hot water blanching led to misleading carotene values, so blanching in steam or in air at 130° C. was preferred. Drying *in vacuo* at 65° C. gave least loss of carotene. By comparison there was a loss of 5 per cent. when samples were dried in air at 65°, 100° or 130° C. Differences in protein content between different treatments were not considered significant.

Carotene concentrations increased with the development of the plants up to the pre-bud stage, then fell, but total carotene per culm increased until seed pods were formed. Protein content

decreased with increasing maturity. The importance is emphasised of sampling at the same stage of maturity in comparative studies. When samples were taken from the same plot in the morning and in the afternoon, sometimes the former had the higher carotene content, and sometimes the latter. Day-to-day variation was observed also. No explanation was found.

Several varieties were compared, some of them during 6 cuttings. No variety was consistently higher than the others in carotene or protein content. Any difference found could be attributed to difference in leafiness.—V. H. Booth.

VITAMIN D

359

COWARD, K. H. and IRWIN, J. O. The second international standard for vitamin D: crystalline vitamin D₃. *Bull. World Health Organiz.*, 1954, 10, 875-894. [Dept. Nutrit., Sch. Pharmacol., Univ. London.] French summary.

Work is reported which was done for the Vitamin D Sub-committee of the Accessory Food Factors Committee (Medical Research Council) to test the suitability of vitamin D₃ for adoption as international standard of reference for vitamin D.

The substances tested were a preparation from pooled samples of vitamin D₃, the current international standard (irradiated ergosterol in olive oil), the purest sample of calciferol obtainable, and the British Standards Institution standard of vitamin D₃. All were tested on rats and the vitamin D₃ preparations on chicks also. In addition the U.S.P. Reference cod liver oil was available for test. Thirty laboratories throughout the world took part. The results were remarkably uniform; they are not set out in detail but the statistical analysis is given, and the final estimates for the potency ratios of the preparations to one another are tabulated.

(For the Report of the meeting of the WHO Expert Committee on Biological Standardization, Subcommittee on Fat-soluble Vitamins, at which vitamin D₃ was recommended for adoption as the international standard of vitamin D see *WHO Tech. Report Ser.* No. 3, Feb. 1950.)

BLISS, C. I., WHITMAN, C., McDONALD, F. G. and BILLS, C. E. Sources of variation in the determination of vitamin D by the line test. *J. Assoc. Off. Agric. Chem.*, 1954, 37, 499-508. [Mead, Johnson and Co., Res. Lab., Evansville, Md.]

Vol. 25, No. 1

The magnitude of certain sources of error was studied in a test with pied rats of the Wisconsin laboratory strain, reared on a diet of 75 parts Mead's Pabulum and 25 parts whole milk powder. Litters were reduced at birth to 8 of which 6 were used. About the age of 21 days they received McCollum's rachitogenic diet No. 3143, which produced florid rickets in 20 days. Some rats were caged in groups and some individually but it was found to make no difference. Vitamin D was given as the U.S.P. Reference Standard Cod-Liver Oil No. 2, diluted with maize oil to give 6 doses increasing by multiples of $\sqrt{2}$ from 1.06 to 6 mg. The doses were given daily for 6 days. The experiment was in 2 series, in each of which it was arranged in 2 Latin squares with 6 doses and 6 rats per dose. In one series the rats of the same litter began to receive their treatment when they had reached a certain age, and in the other when they had reached a certain weight, each group being balanced according to litter for the other variable. At the end of the experiment the radius and tibia from both sides were taken for the line test. Two observers made the readings and scored each bone in grades from 0 to 4 by quarter units on the Bills scale (*Biol. Symposia*, 1947, 12, 409).

Analysis of the results showed that the mean of the results obtained by the 2 observers was the same, but the less experienced observer tended to overscore poor healing and underscore good healing. Subsequently only the more experienced observer's readings were used; the standard deviation of his results showed that differences expressed in terms of even smaller units than those used would have had significance.

The use of bones from the right and left sides had no significant influence. The tibia proved more sensitive than the radius, with which 70 per cent. more rats would have been needed to give the same

degree of significance. In subsequent analysis of the results, only the data for the tibia were used.

The attempt to start treatment when all the rats in the same litter had reached the same weight led to an average range of difference of 19 days in the time spent on the rachitogenic diet before treatment, which was clearly unsatisfactory, and the results obtained in this series were not subjected to further analysis.

Bodyweight, amount of food consumed, and a small loss in weight, at the end of the preliminary period before treatment, had no effect on the degree of healing.

If rats were allotted to doses irrespective of litter, 50 per cent. more of them would be needed to give the same accuracy as when littermates were evenly distributed.

When the mean response to each of the 5 largest doses was plotted against the logarithm of the dose value, a straight line of satisfactory slope was obtained.—E. M. Hume.

YODER, L. and THOMAS, B. H. **An antirachitic sulfonic acid derivative of cholesterol.** *Arch. Biochem. Biophys.*, 1954, **50**, 113-123. [Chem. Sect., Iowa Agric. Exp. Stat., Ames.]

Chlorosulphonic acid was added to cholesterol in glacial acetic acid. The mixture was heated for several hours at a temperature of from 120° to 125° C.; HCl and SO₂ were evolved. The solution was concentrated by distillation, suspended in hot water, and treated with excess Ca acetate. The Ca sulphonates thus formed were further purified, and the brucine salt of a steroid sulphonate was prepared from a benzene solution of the ether-soluble component of them. The brucine salt was characterised. The free steroid monosulphonate and its Na salt were prepared from the brucine salt. The free acid was subjected to bromination, hydrogenation, permanganate oxidation, and perbenzoic acid titration. The absorption spectrum was studied; the maximum was at 230 mμ.

Tested biologically on chicks and rats, the antirachitic potency of the free acid is reported as 25,000 A.O.A.C. units per g.

The evidence was considered to support the

conclusion that the substance was not of the same type as vitamin D₃ or the vitamin in cod liver oil.

CRUICKSHANK, E. M., KODICEK, E. and ARMITAGE, P. **The vitamin D content of tissues of rats given ergocalciferol.** *Biochem. J.*, 1954, **58**, 172-175. [Dunn Nutrit. Lab., Univ. Cambridge.]

Further investigation was made into the fate of a single dose of 1 mg. (40,000 I.U.) vitamin D₂ given orally to rats, of which only 6 per cent. could previously be found (Abst. 4159, Vol. 23). With the same technique as before, 15 rachitic rats were given the dose of 1 mg., and were killed 24 or 48 hr. later. The vitamin D content of the fresh organs and tissues was estimated in tests with 200 other rats. As was found before, the liver with a mean total of 1440 I.U. on the first day contained most of the absorbed vitamin, but there was an appreciable amount also in muscle and skin. The kidneys contained a relatively high concentration. The lungs, spleen, brain and adrenal glands contained little. The mean total amounts in the organs and tissues without the liver and intestines in the present experiment, and in the body as a whole without the liver and intestines in the previous experiment, were, respectively, in I.U. 620 and 690 on the first day, and 890 and 630 on the second day. In the present experiment, the amounts on the first day were greatest in the liver, intestinal tissue and kidneys, and on the second day in the muscles and skin. Other organs were not tested on both days.

It is suggested that the relatively high concen-

N.A. and R., January 1955

tration in the kidneys may be connected with the function of tubular re-absorption.

The results are treated statistically.

TULPUL, P. G. and PATWARDHAN, V. N. **Mode of action of vitamin D. The effect of vitamin D deficiency in the rat on anaerobic glycolysis and pyruvate oxidation by epiphyseal cartilage.** *Biochem. J.*, 1954, **58**, 61-65. [Nutrit. Res. Labs., Indian Counc. Med. Res., Coonoor, S. India.]

Other studies (in the press) led to the conclusion that failure of calcification in vitamin D deficiency is probably due to disturbance in the metabolism of glycogen in cartilage.

To test the conclusion, 180 rats weighing about 45 g. were maintained on a rachitogenic diet low in P; some of them received 25 I.U. vitamin D daily. Rats were killed after 5, 10, 15 and 20 days, and the epiphyseal cartilage of the tibia was removed. With thin slices of it the anaerobic breakdown of glycogen and hexose phosphate, and the aerobic oxidation of pyruvate, were measured with the Warburg manometer. Adenosine triphosphate, diphosphopyridine nucleotide and Mg ions, added to the reaction medium, heightened the activity. For rats in the early stages of rickets, the glycolytic activity of the cartilage was considerably higher than for those given vitamin D. Later the difference disappeared, and it was not as a whole statistically significant. The aerobic oxidation of pyruvate, on the other hand, diminished steadily in rachitic cartilage, and after 20 days seemed to have ceased entirely; in the rats given vitamin D the process was unimpaired.

Tests with liver and kidney homogenates showed no loss of capacity to oxidise pyruvate by rachitic rats.

It is suggested that failure to oxidise pyruvate interferes with the supply of citrate to the bone, and that the significance of citrate in rickets is thus explained.—E. M. Hume.

367

BELLIN, S. A., HERTING, D. C., CRAMER, J. W., PLEGGI, V. J. and STEENBOOK, H. **The effect of vitamin D on urinary citrate in relation to calcium, phosphorus and urinary pH.** *Arch. Biochem. Biophys.*, 1954, **50**, 18-24. [Dept. Biochem., Coll. Agric., Univ. Wisconsin, Madison.]

Rats weighing from 60 to 100 g. were fed on a diet of glucose, cooked egg white, roughage and cottonseed oil, with a salt mixture without Ca or P, and vitamins without vitamin D. Ca was added as CaCO_3 , P as a mixture of KH_2PO_4 and K_2HOP_4 , and vitamin D₂ as 75 I.U. every 3 days.

NaHCO_3 and NaCl were sometimes added. Food consumption was equalised between groups with and without vitamin D. Citrate was estimated in the urine for 3-day periods, and the pH of the urine at the end of the 3-day period. The effect of varying amounts of minerals in the diet was thus studied.

Citrate was always excreted even with the smallest intakes of Ca and P; the amount was always greatest with NaHCO_3 , 6.6 or 10.0 per cent. in the diet. The amount was always increased by addition of vitamin D. Addition of P to a rachitogenic diet did not reproduce the effect of vitamin D in increasing urinary citrate. No correlation was found between excretion of citrate and of Ca or P.

The relation of changes in urinary pH was less clear. Vitamin D increased the urinary pH with diets high in Ca and low in P, but did not do so with diets not of rachitogenic type; it did, however, increase urinary citrate on such diets even when urinary pH was reduced. It is considered possible, notwithstanding, that systemic pH may be raised by vitamin D at the sites of citrate formation in the body.

No conclusion could be drawn as to whether increase in citrate excretion resulted from increased formation or decreased destruction; the authors are inclined to favour the former.—E. M. Hume.

368

DZIEWIATKOWSKI, D. D. **Vitamin D and endochondral ossification in the rat as indicated by the use of sulfur-35 and phosphorus-32.** *J. Exp. Med.*, 1954, **100**, 25-32. [Hosp. Rockefeller Inst. Med. Res.]

Weanling rats were maintained on a rachitogenic diet low in P and were given intraperitoneal injections of ^{35}S and ^{32}P , with or without vitamin D₂. The animals were killed at different intervals afterwards, and the injections of the isotopes and vitamin were spaced in different ways. The serum, urine and portions of the skeleton were analysed as described elsewhere (Abst. 344, Vol. 25). Sulphomucopolysaccharides were estimated in the skeleton and pelt.

The deposition of ^{32}P in the femur and tibia increased from 36 to 48 hr. after administration of vitamin D₂ to vitamin-D-deficient rats. The skeleton immediately incorporated ^{35}S . The rate of synthesis of chondroitin sulphate was the same in both normal and rachitic rats but was increased on administration of vitamin D₂ to deficient rats; in vitamin D deficiency the utilisation of chondroitin sulphate was impaired. The results were held to support the view that "vitamin D directly influences the step in which chondroitin sulfate is used in endochondral ossification".

369

BRONSH, K. Zur Wirkung von Thyroxin auf rachitische Ratten. [The effect of thyroxine on rachitic rats.] *Ztschr. ges. exp. Med.*, 1954, 124, 118-130. [Inst. Physiol. Ernährung Tiere, Univ. Munich.]

Rats weighing about 35 g. were maintained on McCollum's rachitogenic diet. When they showed signs of rickets radiographically, 15 were given 100 I.U. vitamin D₃ for 10 days, 16 received 70 µg. dl-thyroxine by subcutaneous injection daily for 14 days, and 8 received no extra treatment. Basal metabolism was estimated, and 6, 24 and 48 hr. before the animals were killed radio-active Ca and P were given. Blood and tissues were taken for analysis.

The mean B.M.R. of the rachitic rats was 2.3 ± 0.6 Cal. per 10 g. bodyweight in the 24 hr., and the value for those given vitamin D was 3.5 ± 0.5 . In the rachitic rats given thyroxine for 14 days, the B.M.R. rose gradually up to the 6th day, when it reached the value for the rats given vitamin D; it then fell again by the 12th day to the initial value.

The bone ash of the rats given thyroxine was only slightly higher than that of the rachitic rats. In the liver and muscle, the mean value for creatine phosphate was much higher for the rats given thyroxine than for either of the other groups. In the rats given thyroxine, the mean value for phosphatase activity in the tibia was like that of untreated rats, but in the kidneys and duodenum it was nearer to that of rats given vitamin D.

Numerous other results are presented of which the significance is discussed. It is concluded that for the mineralisation of the tissues, especially osteoid tissue, vitamin D and thyroxine must be present in the organism in a balanced equilibrium.

E. M. Hume.

THEOPOLD, W. and SCHULTE-NICKELL, I. Tierexperimentelle Untersuchungen über die antirachitische Wirksamkeit handelsüblicher ultraviolet-bestrahlter Milch. [Animal tests of the antirachitic potency of commercial milk irradiated with ultraviolet light.] *Monatsschr. Kinderheilk.*, 1954, 102, 262-267. [Kinderklinik, Univ. Marburg a.d. Lahn.]

The vitamin D potency of the irradiated milk (Moha milk) supplied to the city of Frankfurt had become a matter of controversy, so, on official request, biological tests were made on milk freshly bought between November 1952 and July 1953.

Groups of young rats were given for 14 days the rachitogenic diet of Steenbock and Black with addition by stomach tube of small daily amounts of the test milk. At the end of the time, the right

hind leg was examined radiographically, and the distal end of the femur histologically. If 80 per cent. of the animals were protected, the test was held to be positive. It was accepted that the protective dose of vitamin D was 1 I.U. daily. Rats gaining less than 2 or more than 22 g. during the experiment were rejected. The test on winter milk offered difficulties, since the potency was much less than expected. Small groups of rats receiving no addition were included but, only in one experiment, a small group given 1 I.U. vitamin D₃ daily. It was concluded that 1 litre irradiated winter milk contained less than 50 I.U. vitamin D.

In the tests in summer, cream (1 ml. = 16.6 ml. milk) and separated milk (0.1 per cent. fat) were tested separately on groups of 10 rats given daily 0.25, 0.5, 1.0 or 1.5 ml. cream, or from 10 to 12 ml. skimmed milk, or 1 I.U. vitamin D₃ or no addition. All the rats given vitamin D₃ or the largest dose of cream were protected, and 8 of those given 1 ml. All the remainder had rickets. The potency of the irradiated summer milk was concluded to be about 80 I.U. per litre, associated entirely with the fat fraction.—E. M. Hume.

RANGANATHAN, S. The vitamin D content of Indian butter. *Indian J. Med. Res.*, 1954, 42, 165-166. [Nutrit. Res. Labs., Indian Council Med. Res., Coonoor, S. India.]

Exceptionally high values for vitamin D in Indian butter and ghee were previously reported (Abst. 1643, Vol. 20). In a further test the unsaponifiable fraction of 3 samples of butter from the Dairy Research Institute, Bangalore was tested by the line test. Groups of 6 rats received 3 doses of the butter and 3 of the international standard. The mean values obtained were 1.20, 1.18 and 1.50 I.U. vitamin D per g. butterfat, which are less than those previously reported and within the normal range.—E. M. Hume.

TAPPEL, A. L. **Studies of the mechanism of vitamin E action. 2. Inhibition of unsaturated fatty acid oxidation catalyzed by haematin compounds.** *Arch. Biochem. Biophys.*, 1954, **50**, 473-485. [Dept. Food Technol., Univ. California, Davis.] Colloidal solutions of linoleate, oleic acid, linseed oil and cod liver oil were made in phosphate butter, usually with the aid of Tween 40. Carotene and vitamin A were similarly emulsified after solution in oleic acid. The oxygen uptake of the solutions was studied in Warburg's apparatus in the presence or absence of haematin compounds, such as haemin, cytochrome *c* and Hb, and with or without the addition of anti-oxidants, such as α -tocopherol, *nordihydroguaiaretic* acid, propyl gallate, butylated hydroxyanisole, methylene blue, thionine and sodium diphenylamine sulphate. Loss of carotene and vitamin A was estimated by spectrophotometry. All the anti-oxidants mentioned, at suitable concentrations, inhibited the oxidation of the fats and fatty acids in the presence of haematin compounds. Against auto-oxidation in the absence of haematin methylene blue gave no protection. α -Tocopherol inhibited the destruction of vitamin A and carotene proportionately with its effect on total oxidation.—T. Moore.

CORDY, D. R. **Experimental production of steatitis (yellow fat disease) in kittens fed a commercial canned cat food and prevention of the condition by vitamin E.** *Cornell Vet.*, 1954, **44**, 310-318. [Sch. Vet. Med., Univ. California, Davis.]

Nine kittens, from 6 to 8 weeks old, were fed on a commercial canned cat food, which consisted largely of fish. The animals grew well at first, but after 6 weeks 2 lost their vitality and appetite and died. The remaining kittens were killed after

8 weeks. Severe steatitis, indicated by an orange-brown colour in all the fat depots, was found in both the animals that died. Histological examination of the affected tissues revealed the deposition of acid-fast pigment, and the presence of many mononuclear cells, mostly macrophages. In one of the other kittens the omental and mesenteric fat was brown, but elsewhere the fat depots were normal. The remaining 5 animals had normal fat. In further experiments 10 more kittens were given the same diet with the addition of 1 ml. fish liver oil daily. Four were given no vitamin E, and 2 each received 10 mg., 20 mg. and 40 mg. of DL- α -tocopherol daily. One of the kittens not given tocopherol died after 4 weeks, and the remaining animals were killed after 16 weeks. The fat was normally coloured in all, except for a faint yellow colour in the animal which died. Microscopic lesions were severe in the same animal, moderate in 2 of the others not given vitamin E, and slight in the fourth. Slight lesions were found in one of the animals given 10 mg. tocopherol daily, but in all the remaining animals, given from 10 to 40 mg. daily, the fat was normal.—T. Moore.

377

SAFFORD, J. W., SWINGLE, K. F. and MARSH, H. **Experimental tocopherol deficiency in young calves.** *Amer. J. Vet. Res.*, 1954, **15**, 373-384. [Agric. Exp. Stat., Montana State Coll., Bozeman.]

Newborn male calves were given a synthetic milk diet without tocopherol after they had had 3 feedings of the dam's colostrum. A capsule containing 74 mg. *d*- α -tocopheryl acetate was given to 2 other calves every 12 hr. after feeding. Vitamins A and D and ascorbic acid were given daily. Electrocardiograms were taken at weekly intervals, and blood was taken weekly for erythrocyte, leucocyte, Hb and α -tocopherol estimations. Urine was tested for creatine, creatinine, albumin and occult blood. Gain in weight was not affected until signs of the deficiency were advanced. Traces of tocopherol appeared unexpectedly in the blood plasma of all 4 of the deprived calves at the occurrence of the most severe signs of deficiency. Body temperature, erythrocyte and leucocyte counts and Hb were not affected by the deficiency of tocopherol. Creatine was present in the urine of the deprived and non-deprived animals. The electrocardiogram tracings of the deprived calves had an average P—R interval of 0.139 sec. and an average Q—T interval of 0.319 sec. The

corresponding average values for the non-deprived calves were 0.109 and 0.286. Only one of the deprived calves had changes in the kidneys.

378

TRIBE, D. E. Observations on the feeding behaviour of rats and chicks deficient in vitamin E. *J. Hyg.*, 1954, 52, 315-320. [Sch. Vet. Sci., Univ. Bristol.]

For 56 days, rats were offered daily in two pots a diet deficient in vitamin E. At the end of the time one of the pots was filled with a diet containing an adequate amount of vitamin E. Vitamin E deficiency was confirmed by the dialuric acid haemolysis test. The rats showed no preference for the adequate diet; the weekly selections from the two pots showed precisely the same pattern in the second period as in the first.

In a second experiment with chicks the development of encephalomalacia was used as criterion of vitamin E deficiency, and a similar result was obtained.—R. J. Ward.

379

MASON, K. E. and DRU, M. Y. Newer knowledge of the metabolism of tocopherols in human tissues. *Nat. Vitamin Found., Inc., N.Y., Nutrit. Symposium Ser. No. 7*, 1953, 1-19. [Sch. Med. Dent., Univ. Rochester, N.Y.]

Total lipids, total tocopherols, γ - and δ -tocopherols, and α -tocopherol by difference, were estimated in over 1100 specimens of human tissues, usually obtained at autopsy. α -Tocopherol invariably predominated, and the amounts of the other forms were often negligible.

In whole foetuses aged from 2 to 6 months total tocopherols amounted on the average to 0.32 mg. per 100 g. fresh tissue. The placenta had on the average 0.71 mg., the skeletal muscles 0.59 mg. and the liver 0.57 mg. In infants, 18 premature and 6 full-term, the average values per 100 g. tissues and per g. fat were 2.14 and 0.07 mg. for adipose tissues, 0.97 and 0.28 for liver, 0.76 and 0.35 for heart, 0.61 and 0.30 for lung, 0.60 and 0.24 for kidney and 0.60 and 0.32 for intestine. In older children and adults who had died from accident or disease, much higher levels were found than in infants. At 4 to 10 years the average levels per 100 g. muscle, heart, liver and adipose tissue were 1.07, 1.33, 1.52 and 5.21 mg., respectively, at 12 to 18 years 0.97, 1.03, 1.48 and 9.11, at 23 to 52 years 1.24, 1.15, 2.08 and 8.31, and at 61 to 93 years 0.93, 1.07, 0.89 and 6.09 mg. In endocrine glands and other visceral organs collected from adults tocopherols amounted on the average to 13.17 mg. per 100 g. tissue and 0.73

mg. per g. fat in adrenals, 4.04 and 1.24 in pituitary, 4.01 and 1.01 in testis, 1.10 and 0.62 in ovary, 1.81 and 0.31 in pancreas, 0.85 and 0.72 in uterus, 0.81 and 0.34 in spleen, 0.68 and 0.28 in kidney and 0.37 and 0.19 in lung.

No evidence of deficiency of tocopherol was found in patients with muscular dystrophy. The daily intake of α -tocopherol in a healthy human adult is estimated as about 25 mg., which may be compared with a total of 20 mg. found in a still-born child.—T. Moore.

GRAY, D. E. and DE LUCA, H. A. Effect of vitamin E on carbohydrate metabolism of rat diaphragm. *Canad. J. Biochem. Physiol.*, 1954, 32, 491-497. [Dept. Biochem., Univ. W. Ontario, London.]

Rats were given a diet deficient in vitamin E, with no supplement, or 0.5 mg. or 100 mg. vitamin E daily. The supplements had no effect on carbohydrate metabolism of the diaphragm incubated with glucose, with or without insulin, except that there was a small difference in the amount of pyruvic acid accumulated during incubation without insulin, the respective values for the 3 groups in the order above being 1.13, 1.42 and 1.30 μ M pyruvic acid per g. wet tissue.

R. J. Ward.

DE ROSA, R. L'azione dell'alfa-tocopherolo nella intossicazione sperimentale da piombo. Comportamento della coproporfirinuria e della crisi ematica. [The effect of alpha-tocopherol on experimental lead poisoning. Behaviour of urinary coproporphyrin and of the blood picture.] *Acta vitaminol.*, 1954, 8, 167-172. [Ist. Med. Lavoro, Univ. Naples.] French, English, German and Spanish summaries.

Of 2 groups of 4 rabbits fed on a normal diet of herbage, and given every other day 200 mg. lead acetate, one group was given 200 mg. α -tocopherol by intramuscular injection every fourth day. Coproporphyrin was estimated in the urine, and blood counts were made, at intervals up to 37 days on such animals as survived so long. All the rabbits given tocopherol were alive on the 37th day; none of those not given it were. The mean amount of coproporphyrin in the urine in 24 hr. did not rise above 70 μ g. in the rabbits given tocopherol, but in those not given it, it reached 350 μ g. The development of anaemia did not show such a marked difference, but was more rapid in the rabbits not given tocopherol.—E. M. Hume.

VITAMIN K

382

UEHARA, K., MURAMATSU, I. and MAKITA, M. Vitamin K₃ as a coenzyme. *Proc. Japan Acad.*, 1953, 29, 511-512. [Dept. Pharmacol., Coll. Med., Univ. Osaka.]

Vitamin K₃, 2-methyl-1:4-naphthoquinone, stimulated the oxidation of phosphogluconate by yeast autolysate, as measured by oxygen uptake in a Warburg apparatus. Unsubstituted naphthoquinone was inactive.—E. M. Hume.

383

TALMAS, V. Naphtylamines, quinones, phénols et temps de saignement moyen. [Naphthylamines, quinones, phenols and mean bleeding time.] *Arch. internat. Pharmacodyn.*, 1953-54, 96, 365-385. [Inst. Clin. Méd., Univ. Liège.]

In rabbits both α - and β -Na naphthylamine-4-sulphonate reduced the bleeding time significantly after a latent period of under 15 min., and over 30 min., respectively; when the former compound was oxidised the latent period disappeared. The naphthoquinones and the naphthohydroquinones, including Synkavit, had an immediate effect in doses ranging from 50 mg. to 10 μ g. per kg. body-weight. Most phenols and quinones tested had also an immediate haemostatic effect. The significance of the findings is discussed.—L. Wills.

RUTQUIST, L. and BÖRNFORS, S. Jämförande undersökningar av olika K-vitaminers inverkan på av dicoumarolpreparat framkallad hypoprothrombinämi hos hund. [Comparative studies of the effect of different vitamin K preparations on prothrombin in the blood of dogs treated with dicoumarol.] *Nord. Vet. Med.*, 1954, 6, 511-519. [Kungl. Vet. Högsk., Stockholm.] English and German summaries.

The preparations tested were: Inj. K-vimin, Astra; Ido-K, Ferosan; and vitamin K₁ (Mephytone), Merck. Of the first 2, 1 ml. contained 10 mg. active substance; the third, the natural vitamin, was used in an oil emulsion of which 1 ml. contained 50 mg. active substance.

The tests were made on 10 dogs given by mouth from 2 to 3 cg. Dicusat (3-(α -acetylbenzyl)-4-oxydicoumarol) per kg. bodyweight. When the prothrombin value had fallen the test substances were given. Vitamin K₁ was immediately effective by mouth or intravenous injection but not by intramuscular injection. Both synthetic preparations given by intravenous injection were without effect. [An earlier paper (*ibid.*, 423; 433) describes the effect of dicoumarol in dogs and records that the Swedish synthetic vitamin K preparation,

Inj. K-vimin, Astra, had no effect on prothrombin time or the haemorrhage produced.]—I. Leitch.

385

BORNSTEIN, S. and SAMBERG, Y. Field cases of vitamin K deficiency in Israel. *Poultry Sci.*, 1954, 33, 831-836. [Govt. Poultry Field Lab., Tel Aviv, Israel.]

It is suggested that outbreaks of vitamin K deficiency, which occurred on diets considered standard for the country, may have resulted from the use of drugs to combat coccidiosis which interfered with the normal intestinal synthesis of vitamin K.—E. M. Cruickshank.

MULÉ, F. and GARUFI, L. Azione della vitamina K sul consumo di ossigeno del miocardio di coniglio in presenza di tossina diphtherica. [Effect of vitamin K on the oxygen consumption of the rabbit's myocardium in presence of diphtheria toxin.] *Bol. Ist. sieroterap. milan.*, 1954, 33, 174-178. [Ist. Prima Clin. Pediat., Univ. Rome.] English summary.

Of 30 rabbits weighing about 2 kg., 10 had no treatment, and 20 were given 1/10 m.l.d. of diphtheria toxin every other day. Readings on the electrocardiogram were taken daily until evidence of myocardial injury was plain, when all the rabbits were killed. The oxygen consumption by emulsions of the heart muscle was measured in a Warburg apparatus with and without addition of a solution of 100 μ g. vitamin K per ml. saline, and with and without addition of diphtheria toxin. The oxygen consumption of normal heart muscle was increased by presence in the medium of diphtheria toxin, and progressively more so with increasing concentration; the effect was less in rabbits previously treated with diphtheria toxin. The presence of vitamin K in the medium had no effect on normal heart muscle but tended to counteract the effect of diphtheria toxin.—E. M. Hume.

MEISEL, M. N. and POMOSHNIKOV, N. A. Primenenie radioizotopov dlya uskorenogo mikrobiologicheskogo opredeleniya vitaminov. [Use of radio-isotopes for the rapid microbiological estimation of vitamins.] *Dokl. Akad. Nauk S.S.S.R.*, 1953, **91**, 953-955. [Inst. Mikrobiol., Akad. Nauk SSSR.]

Experiments showed that, in certain conditions, the rate at which radio-active P was assimilated by proliferating yeast cells reflected during the first hours the rate of growth and cell proliferation, and actually preceded the growth process by a few hours. Energetic growth did not start until from 4 to 6 hr. after seeding, and the assimilation of P from the media used attained its maximum within that time. On this principle was based a tentative method for estimating pantothenic acid with *Saccharomyces ludwigii* and vitamin B₆ with *Saccharomyces carlsbergensis* 4228. The time required for an analysis was reduced from 40 to 48 hr. to from 4 to 6 hr. The calibration process adopted for pantothenic acid was as follows. The indicator culture was grown for 2 days at 28° C. on a sugar and mineral Rider medium containing normal amounts of the necessary vitamins apart from pantothenic acid, which was added only in trace amounts of 0.004 µg. per ml., in order to obtain a culture particularly sensitive to it. The culture thus obtained was filtered, and washed with sterilised conductivity water, pressed and then added to the test flasks. For each 100 ml. medium, 100 mg. pressed yeast with from 1 to 2.5 µC. Na₂H³²PO₄, and different amounts of pantothenic acid, were added. After 6 hr. at from 27° to 28° C. the yeast was separated by centrifuging, washed 4 times with water and suspended in 10 ml. water; 0.1 ml. of the suspension was then tested with a Geiger counter. The results showed that a calibration curve could be drawn for estimating pantothenic acid from the radio-activity of the yeast suspension.—W. Hughes.

HUNT, C. H., BENTLEY, O. G., HERSHBERGER, T. V. and CLINE, J. H. The effect of carbohydrates and sulfur on B-vitamins synthesis, cellulose digestion, and urea utilization by rumen micro-organisms *in vitro*. *J. Animal Sci.*, 1954, **13**, 570-580. [Dept. Animal Sci., Ohio Agric. Exp. Stat., Wooster.]

Rumen fluid from 2 steers with a rumen fistula, one fed on good alfalfa hay and one on poor timothy hay, was used for experiments in an artificial rumen. Cellulose digestion, utilisation of urea and formation of riboflavin, pantothenic acid, nicotinic acid and vitamin B₁₂ were studied.

Addition of starch to the flasks reduced the amount of cellulose digested, but increased synthesis of riboflavin and utilisation of urea. With or without starch, less riboflavin was present after 48 hr. than after 24 hr., but more was present after 96 hr. Cellulose digestion and urea utilisation were complete after 48 hr. in most experiments. More cellulose was digested and more urea was used when the inoculum came from the steer fed on alfalfa hay than when it came from that on poor hay. Sulphur added as sodium sulphate or methionine in the presence of starch increased the amounts of riboflavin, nicotinic acid and vitamin B₁₂ formed. Glutathione was not effective. Aureomycin inhibited the formation of riboflavin, nicotinic acid and pantothenic acid, but not that of vitamin B₁₂. Cystine and elemental S were less effective in stimulating vitamin synthesis than methionine and sulphate. All the S compounds, but not elemental S, reduced the amount of pantothenic acid synthesised; it is concluded that pantothenic acid is formed by organisms other than those that make the other vitamins.

Ethionine reduced the activity of all the micro-organisms.—D. Duncan.

BEARE, J. L., BEATON, J. R. and McHENRY, E. W. Anterior pituitary growth hormone administration in B vitamin deficiencies in the rat. *Endocrinology*, 1954, **55**, 40-44. [Dept. Pub. Health Nutrit., Univ. Toronto.]

Anterior pituitary growth hormone was administered to rats on diets lacking certain members of the vitamin B complex. Rats deprived of

riboflavin or pantothenic acid failed to respond to it, as was shown by their failure to increase in weight, but in controls receiving riboflavin and Ca pantothenate it promoted weight gain and N retention. Animals deprived of vitamin B₁ responded to growth hormone. In all the groups fasting blood urea was depressed by administration of it. The results showed the necessity for considering the constituents of the diet, as well as the amount of food consumed, when investigating the effects of growth hormone.—M. B. Richards.

LEVY, H. A., DiPALMA, J. R. and ALFER, C. The effects of nutritional deficiency on response to thiopental. *J. Pharmacol. Exp. Therap.*, 1953, 109, 377-386. [Div. Pharmacol., Hahnemann Med. Coll., Philadelphia, Pa.]

The response to thiopental was measured by a simple device which is described. For comparative studies a standard dose producing a standard result was established after a large number of trials on many normal animals. In mice deprived of the vitamin B complex or of riboflavin, pyridoxine or pantothenic acid, the response was moderately increased; a complete diet for 2 weeks restored the response to normal in all the animals except those deprived of pantothenic acid, which required a longer period before normal function was restored. Acute protein starvation had a similar effect. Vitamin B₁ deficiency had no significant effect on the response. Mice rendered deficient in nicotinic acid by deficient diet or by a nicotinic acid inhibitor showed a greatly enhanced response, though nicotinic acid itself had no analeptic action and did not depress the response to thiopental. It is suggested that in nicotinic-acid-deficient mice the metabolism of thiopental is abnormal because of interference with the action of dehydrogenases linked to pyridine nucleotide.—L. Wills.

EVANS, W. C., EVANS, E. T. R. and HUGHES, L. E. Studies on bracken poisoning in cattle. 2. 1950 Bracken poisoning experiments (Lluest farm). *Brit. Vet. J.*, 1954, 110, 365-380. [Dept. Agric. Chem., Univ. Coll. North Wales, Bangor.]

Five yearling Shorthorns were fed on a diet of hay and high-protein cake with chaffed bracken equivalent in weight to the hay consumed. All of them, including two which received molasses also, died of typical bracken poisoning. A transient rise in temperature was noticed some weeks before the terminal pyrexia. Three others, fed on the same diet except that the bracken had been steamed for from 30 to 45 min., survived; they consumed greater quantities of feed than those given untreated bracken.

Vol. 25, No. 1

All the animals having unsteamed bracken developed pronounced leucopenia, thrombocytopenia and haemorrhages. The polymorphonuclear leucocytes were the first to be grossly diminished and terminally, the non-granular cells also were affected. There were also defects in clot retraction and increased capillary fragility. Terminally, there was a sharp rise in blood pyruvate. The animals having steamed bracken remained normal for the 84 days of the experiment. The tissues of bracken-poisoned animals had a content of vitamin B₁ lower than normal, but were not grossly depleted, and the classical signs of deficiency were absent.

Four heifers were used to test the efficacy, as therapeutic agents for bracken poisoning, of nicotinamide given orally or parenterally, folic acid, a liver extract containing vitamin B₁₂, ascorbic acid, vitamin B₁, and many other components of the vitamin B complex. All were found valueless. The same animals were used to follow the lesions in the bone marrow which preceded the blood changes; granulocytic and thrombocytic aplasia occurred, and terminally there was some interference with the erythrocyte precursors.

Blood cultures were made at critical periods in the course of the disease. Several organisms were isolated, but there was no correlation between positive cultures and occurrence of fever. The faeces at no time contained salmonella or significant numbers of worm eggs, and filtrates of bowel contents at death were not harmful to mice.

W. A. Greig.

396

PHILLIPSON, A. T. and REID, R. S. Studies of the toxicity of bracken (*Pteris aquilina*). *J. Comp. Pathol.*, 1954, 64, 243-259. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]

Samples of rumen contents from 2 heifers, one given a ration of which 60 per cent. was sun-dried bracken and the other given hay, were strained through gauze and centrifuged to give a sludge which was tested fresh on weanling rats given a diet deficient in vitamin B₁. In later experiments the sludge was boiled for 15 min. at pH between 1 and 2 to destroy thiaminase. The neutralised supernatant fluid was concentrated and added to the sludge.

Rats given 12 per cent. of the diet on a dry matter basis as sludge from the heifer fed on bracken did not gain weight. Injections of vitamin B₁ gave an immediate response. With sludge from the normally fed heifer as 8, 12 or 16 per cent. of the diet, optimum or slightly suboptimum weight gain was obtained.

Rats given 40 per cent. of the diet as bracken and receiving vitamin B₁ injections grew normally, but with 60 per cent. they made only small weight gains.

The heifer fed on dried bracken showed no sign

4

of bracken poisoning after 66 days and the mixed ration was replaced by fresh bracken only. In previous work with 15 heifers fed on bracken, all but one showed signs of poisoning and only one recovered; there were no definite signs of vitamin B₁ deficiency and blood pyruvate did not rise significantly until from 24 to 48 hr. before death.

A. Hepburn.

MITTLER, S. Influence of vitamins upon incidence of tumors in tu⁵⁰¹ stock of *D. melanogaster*. *Science*, 1954, 120, 314. [Armour Res. Found., Illinois Inst. Technol., Chicago.]

It had been found previously that poor nutrition reduced the incidence of tumours in a susceptible stock of *Drosophila melanogaster*. The effect was studied of adding specific vitamins to a restricted medium in which the only source of nutrient was the yeast *Hansenula anomala*. Significant increases in tumour incidence occurred in flies reared with an excess of vitamin B₁₂, riboflavin, *p*-aminobenzoic acid, pyridoxine or pantothenic acid. A diet of maize meal and molasses also increased the number of tumours. No explanation is yet suggested for the effect of a more ample diet in promoting tumour formation.—A. M. Copping.

SLINGER, S. J. and PEPPER, W. F. The effect of antibiotics on the turkey poult's need for supplementary biotin and pantothenic acid. *Poultry Sci.*, 1954, 33, 633-637. [Dept. Poultry Husb., Ontario Agric. Coll., Guelph.]

Turkey poults, reared for 4 weeks in a normal way on a practical diet adequate in vitamin B₁₂,

grew poorly and had a high incidence of broken feathers, diarrhoea and dermatitis. Mortality also was high. When the diet was supplemented with aureomycin and vitamin B₁₂, growth and efficiency of utilisation of feed increased, the disorders disappeared, and mortality fell. In another experiment, poults were given a good basal diet containing 0.094 mg. biotin per lb., or this diet supplemented with different amounts of biotin with or without antibiotics. Growth increased with increase in the biotin supplement, maximum weight being attained with 0.30 mg. biotin per lb. feed. When terramycin or penicillin was given in addition, maximum weight was attained with as little as 0.04 mg. of added biotin. Efficiency of feed utilisation was not improved by biotin in presence or absence of antibiotics. Penicillin reduced the poult's requirement of Ca pantothenate also. About 5.24 mg. pantothenic acid per lb. feed was adequate for good growth and to prevent dermatitis, but more was necessary for optimum feather development.—E. M. Cruickshank.

401

ADRIAN, J. Teneurs de l'œuf de poule en riboflavine, niacine et acide pantothenique. Variabilité et corrélations. [Content of riboflavin, nicotinic acid and pantothenic acid in the hen's egg. Variability and correlations.] *Ann. Zootech.*, 1952, 1, No. 3, 17-29. [Lab. Biochim. Nutrit., C.N.R.S., Bellevue, Seine-et-Oise.]

Riboflavin, nicotinic acid and pantothenic acid were estimated microbiologically in eggs bought in the open market or obtained from hens on controlled diets. The eggs were plunged into boiling water and cooked for 10 min. so that white and yolk could be completely separated. The average amounts in μ g. per whole market egg (average weight 48.9 g.) were nicotinic acid 29.45, riboflavin 224.2, and pantothenic acid 968.5. Similar values were found in eggs from hens of a known stock. Nicotinic acid and riboflavin were present in greater total amount in the white, and pantothenic acid in greater amount in the yolk. In balance experiments with 7 Rhode Island hens, the eggs contained 11.4 per cent. of the riboflavin supplied by the diet, 0.065 of the nicotinic acid and 25.2 of the pantothenic acid. There was a correlation between the riboflavin and pantothenic acid contents of the egg, but the nicotinic acid content was not related to that of the other B vitamins. From the point of view of the vitamin B complex, eggs were good sources of riboflavin and pantothenic acid, but made only a very small contribution of nicotinic acid to the diet of man.

ZIMA, O. and GÖTTMANN, G. Oxydationsprodukte der Phosphorsäureester des Aneurins. [Oxidation products of vitamin B₁ phosphoric acid esters.] *Naturwissenschaften*, 1954, **41**, 214. [Forschungslab., E. Merck A.G., Darmstadt.]

A preliminary report is made on the preparation of the disulphides of vitamin B₁ phosphoric esters with chlorine or H₂O₂ as oxidising agent instead of iodine. The resulting disulphide of the orthophosphoric ester of vitamin B₁ was active in the redox test by the Warburg method, but the orthophosphoric ester itself had little activity. The disulphide of the pyrophosphoric ester was somewhat less active by the Warburg method than the pyrophosphoric ester, cocarboxylase, itself. The disulphides of both esters could be reduced by cysteine and split by diastase to give products which behaved like vitamin B₁ disulphide and did not give the thiochrome reaction. Treatment with cysteine yielded the amount of vitamin B₁ expected.

FUJIWARA, M., WATANABE, H. and MATSUI, K. "Allithiamine," a newly found derivative of vitamin B₁. 1. Discovery of allithiamine. FUJIWARA, M., NANJO, H., ARAI, T. and SUZUKI-ZIRO. 2. The effect of allithiamine on living

organism. *J. Biochem., Tokyo*, 1954, **41**, 29-39; 273-285. [Dept. Hyg., Fac. Med., Univ. Kyoto.]

1. The substance in garlic which gives rise to allithiamine is distinguished from antivitamin B_1 as having only a masking effect; it does not destroy the biological activity of vitamin B_1 but destroys its response in the thiochrome reaction. The structure has been determined and the substance synthesised. The present paper summarises the history of allithiamine (see Absts. 312, 313, Vol. 23).

The extract from 0.1 g. *Allium sativum* prevented the response of 800 μ g. vitamin B_1 in the thiochrome reaction; the optimum pH was about 8, and the optimum temperature from 60° to 70° C. Presence of oxygen was not necessary. An extract of unground, boiled garlic exerted no masking action; addition of protein from ground, raw garlic restored the activity, but the protein had no activity alone.

Allithiamine was isolated by extracting raw garlic bulbs with 99 per cent. ethanol, and adding vitamin B_1 in water to the extract. Ultimate extraction of allithiamine was with ether. The substance was analysed and characterised, and a formula was allotted to it. It could be estimated by the thiochrome reaction after reduction with cysteine or other suitable agent. It was reduced by human blood.

It is reported that other species of *Allium*, some members of the Cruciferae, and animal saliva and gall contain substances which mask the thiochrome reaction.

2. Synthetic allithiamine (thiamine allyl disulphide) and an analogue were less toxic for mice in very large doses than vitamin B_1 itself.

Four groups of 5 young rats were given a diet deficient in vitamin B_1 with daily addition of 40 μ g. vitamin B_1 or of 42 μ g. thiamine allyl disulphide or its analogue or no supplement. The last group were all dead within 4 weeks. In 5 weeks the mean weight of the other groups was, respectively, 118, 127 and 132 g. Two further experiments confirmed the result. The 3 substances were equally effective in curing bradycardia in rats deprived of vitamin B_1 , and convulsions in pigeons similarly deprived.

When groups of 2 human subjects were given orally for a week at a time 0, 2, 5, 10 or 20 mg. daily of one of the 3 substances, the urinary excretion of vitamin B_1 rose with increasing dose more slowly with vitamin B_1 than with the other 2 substances, neither of which was ever excreted unchanged. Faecal excretion of vitamin B_1 , on the other hand, was greatest after administration of it.

After intravenous injection into human subjects and rabbits, the blood concentration of vitamin B_1 rose more rapidly, and remained high longer, par-

ticularly in the cells, with allithiamine than with vitamin B_1 .

After oral ingestion, the concentration of vitamin B_1 in most organs and tissues of rats was higher with allithiamine than with vitamin B_1 . In the livers of rats the percentage of phosphorylated vitamin B_1 was greater after administration of allithiamine than of vitamin B_1 . It is considered that the differences in effect of allithiamine result from its more rapid spread in tissues.

HILL, R. M. and HOLTKAMP, D. E. Storage of dietary manganese and thiamine in the rat. *J. Nutrition*, 1954, **53**, 73-82. [Dept. Biochem., Univ. Colorado Med. Centre, Denver.]

Ten groups of adult rats received for 24 weeks a basal diet supplying from 0.03 to 40.0 mg. Mn daily. In some groups the intake of vitamin B_1 was kept constant at 0.03 mg. daily and in others it was one-fifth of the Mn intake. Two other groups received for 4 weeks stock diet supplying 1.1 mg. Mn and 0.05 or 8.0 mg. vitamin B_1 . Estimations were made of Mn by Ray's method (Abst. 2330, Vol. 10) and of vitamin B_1 by the manometric method of Atkin *et al.* (Abst. 2897, Vol. 9) in the liver and small intestine, and sometimes in the caecum and colon. Dietary Mn had no effect on co-carboxylase content and results are given as total vitamin B_1 .

The storage of vitamin B_1 in the liver increased with increasing intake of Mn and vitamin B_1 up to a daily intake of 10 mg. and 2.0 mg., respectively. Maximum content of vitamin B_1 was between 11 and 16 μ g. per g. fresh liver tissue. A greater storage occurred in adults aged 13 weeks than in those aged 36 weeks. When the intake of vitamin B_1 was kept constant, increase of Mn intake up to 1.0 mg. daily increased the storage of vitamin B_1 in the liver.

Storage of Mn in the liver was increased, but not proportionately, with increase of Mn intake up to 40.0 mg. With a constant Mn intake of 1 mg., Mn increased slightly in the liver with increase of vitamin B_1 from 0.03 to 0.02 mg. daily. There was no apparent maximum value for the Mn content of the liver.

The content of Mn in the intestinal tissue depended on the dietary intake, and with small intakes the values per g. were about half those in the liver; with 10 mg. daily storage was greater than in the liver. The content per g. in the caecum and colon was at least as great as in the liver. There was some evidence that Mn was more readily absorbed at low than at high concentrations.—V. R. Jackson.

MCCARTHY, P. T., CERECEDO, L. R. and BROWN, E. V. The fate of thiamine- S^{35} in the rat. *J.*

N.A. and R., January 1955

Biol. Chem., 1954, **209**, 611-618. [Dept. Chem., Fordham Univ., New York.]

Vitamin B₁ labelled with ³⁵S was injected into rats having diets with or without the vitamin. Urine was collected for 10 days after administration of the radio-active vitamin and the distribution of the radio-activity was measured in the inorganic sulphate, etheral sulphate and neutral sulphur fractions. Normal rats excreted 64-38 per cent. of an injection of 50 µg. vitamin B₁ with 62 per cent. of the radio-activity in the neutral sulphur fraction. Deprived rats excreted 52 per cent. of the amount injected, 46-5 per cent. being in the neutral sulphur compounds. A very little radio-activity was found in the faeces, and small amounts were present in all organs and tissues which contained vitamin B₁. The greatest amounts were found in muscle.

When oxythiamine was injected into depleted rats 24 hr. after an injection of radio-active vitamin B₁, the utilisation and oxidation of the vitamin were disturbed and a higher proportion of the radio-activity was recovered from the neutral sulphur compounds of the urine.

STURKIE, P. D. Effects of acute thiamine deficiency on the electrocardiogram of the chick. *Poultry Sci.*, 1954, **33**, 508-510. [Lab. Avian Physiol., Rutgers Univ., New Brunswick, N.J.]

Three groups of White Leghorn chicks, 2 and 12 days old, were given a synthetic diet without vitamin B₁. About 50 per cent. died within 15 days, and most of them were dead after 28 days. Heart abnormalities developed within from 7 to 10 days. Sinus arrhythmia appeared in the early stages of deficiency, and was followed by sinus arrest and bradycardia. The heart rate, normally from 250 to 300 beats per min., was reduced to from 90 to 100 in moribund chicks. Other abnormalities recorded were depression of the S-T

segment, and occurrence of ectopic beats and A-V dissociation with nodal rhythm.

E. M. Cruickshank.

416

FEKETE, G. and PRÓKAI, A. Effect of vitamin B₁ on changes due to chronic adrenal treatment. *Acta physiol. hung.*, 1954, **6**, 41-46. [Inst. Pathophysiol., Med. Univ., Szeged.] Russian summary.

The effects of continued adrenaline treatment, which reduces the growth rate and food intake of rats, were not influenced by giving vitamin B₁. Marked differences were found between cortisone and adrenaline in their effects on the weights of the organs. Cortisone reduced the weight of the heart, adrenal glands, spleen and thymus, but adrenaline reduced the weight only of the thymus; the weight of the spleen remained unchanged, and that of the heart and adrenal glands increased. The organ weights of the animals receiving adrenaline and vitamin B₁ were similar to those of the animals receiving adrenaline only, except that the thymus atrophy induced by adrenaline was inhibited by vitamin B₁. The results suggest that the mechanisms underlying "stress" and the effects of adrenocorticotrophic hormone and adrenaline are different. It is believed that vitamin B₁ causes structural changes in the adrenocorticotrophic hormone molecule *in vivo*.

STEYN-PAARVÉ, E. P. The influence of feeding oxythiamine on the thiamine pyrophosphate content of some tissues of the pigeon. *Biochim. biophys. Acta*, 1954, **14**, 440-441. [Lab. Physiol. Chem., Univ. Utrecht.]

Two groups of 6 pigeons received 2 g. casein and 18 g. sucrose daily, with a salt mixture, and vitamins including 100 µg. vitamin B₁ daily; one group received in addition 1 mg. oxythiamine daily. After 15 days the birds were killed and manometric estimation was made of vitamin B₁ pyrophosphate in the liver, heart and breast muscle, and brain; none of them showed any pronounced sign of vitamin B₁ deficiency.

In birds receiving oxythiamine there was a significant decrease in the vitamin B₁ pyrophosphate content of the heart and breast muscle corresponding to a vitamin B₁ deprivation of 4 days' duration, and a non-significant decrease in the liver and brain. Another, similar test confirmed the results.—V. R. Jackson.

418

CERCOBDO, L. R., EICH, S. and BRESNICK, E. Effects of oxythiamine and neopyrithiamine on phosphorylation of thiamine by thiamine phosphorylase from rat intestine. *Biochem. biophys. Acta*, 1954, **15**, 144-145. [Dept. Biochem., Fordham Univ., New York.]

The formation of cocarboxylase from vitamin B₁ in a system containing Mg, adenosine triphosphate and phosphorylase from rat intestine was inhibited by neopyrithiamine but not by oxythiamine. From other unpublished results it appeared that inhibition of phosphorylation depended on the presence of an amino-group in position 4 of the pyrimidine nucleus of the analogue.

ONRUST, H., VAN DER LINDEN, A. C. and JANSEN, B. C. P. Triphospho-pyrithiamine and p-chloromercuribenzoate in a study of the prosthetic groups of the pyruvic acid oxidase of animal tissue. *Enzymologia*, 1954, 16, 289-297. [Netherlands Inst. Nutrit., Amsterdam.]

In a previous study (Abst. 4195, Vol. 23) it was found that diphosphothiamine and triphospho-oxythiamine completely inhibited pyruvic acid dehydrogenase in animal tissue. A similar effect was obtained with triphosphopyrithiamine but the inhibition was incomplete. As was found before, re-activation was possible in the presence of yeast. Inhibition of the pyruvic dehydrogenase was found also with p-chloromercuribenzoate; it was re-

versed with glutathione or thiomalic acid but not with thiamine or diphosphothiamine, which suggested that the SH groups required were not available from diphosphothiamine. The nature of the inhibition is discussed with reference to the redox potentials of the systems involved.

GADEN, E. L. (Jr.), PETSLAVAS, D. N. and WINOKER, J. Microbiological production of riboflavin and citric acid from citrus molasses. *J. Agric. Food Chem.*, 1954, 2, 632-638. [Dept. Chem. Eng., Columbia Univ., New York 27.]

Attempts were made to produce citric acid by cultivation of *Aspergillus niger* on raw and refined citrus molasses, which is the syrup obtained by evaporating the "press water" by-product of citrus fruit processing. The result was unsatisfactory, and the failure was attributed to the high cation content of the molasses; small amounts were found when Cu and Fe were removed by ion exchange. Fermentation time was reduced and yields were higher if a vegetative inoculum was used, but only 35 per cent. of the theoretical amount was produced in 4 days and the purification required made the procedure commercially unprofitable.

Ashbya gossypii did not produce riboflavin from raw molasses in the conditions of the test, but in preliminary tests *Eremothecium ashbyii* synthesised substantial amounts when the sugar concentration ranged from 2.1 to 4.25 per cent., and 0.3 per cent. of yeast extract had been added. The yield was highest with the highest sugar concentration. Further tests with vegetative inoculum showed that the optimum pH value was 7; the yield did not decrease as rapidly at higher as at lower pH

values. The optimum initial sugar concentration was 6 per cent.; fermentation for 9 days gave considerably higher yields than for 6, up to 720 µg. per ml. Added peptone had no effect and bone glue was detrimental. The course of riboflavin production throughout fermentation is described.

V. R. Jackson.

422

KLUNGSÖYR, L. The biosynthesis of riboflavin in *Eremothecium ashbyii*. *Acta chem. scand.*, 1954, 8, 723-727. [Biochem. Lab., Univ. Clin., Bergen.]

When incubated in a solution of inorganic salts, washed mycelium of *Eremothecium ashbyii* produced significant amounts of riboflavin, which was evidently a metabolic product in the already formed cells.

A liquid medium was inoculated with the organism and shaken for 24 hr.; 10 µC. 1-¹⁴C acetate were then added and the shaking was continued for a further 72 hr. After butanol extraction and precipitation with light petroleum, carrier riboflavin was added and the labelled product was crystallised. Less than 0.01 per cent. of the added ¹⁴C was recovered from the riboflavin.

A small amount of radio-active riboflavin was made alkaline, degraded by the action of light and then hydrolysed. The resulting products were extracted and separated by paper chromatography. They consisted of lumiflavin and lumichrome

N.A. and R., January 1955

which had high activity while the hydrolysis product of the lumiflavin had not. Similar results were obtained with washed myosium. Carbon no. 2 in the riboflavin nucleus is lost when lumiflavin is hydrolysed, so it evidently was the one which was labelled. A tentative scheme for the incorporation of acetate into riboflavin by way of the purine nucleus is suggested.—A. Hepburn.

423

PLAUT, G. W. E. Biosynthesis of riboflavin. 1. Incorporation of C^{14} -labeled compounds into rings B and C. *J. Biol. Chem.*, 1954, 208, 513-520. [Inst. Enzyme Res., Univ. Wisconsin, Madison.]

The yeast *Ashbya gossypii*, which synthesises riboflavin, was used and, when the rate of riboflavin production was at a peak, compounds labelled with ^{14}C were added to the medium. Degradation procedures were elaborated for identifying C atoms from rings B and C of the riboflavin molecule. The pattern of incorporation of ^{14}C from specific precursors into rings B and C showed a striking resemblance to the pattern of incorporation observed in the pyrimidine portion of uric acid (Title 892, Vol. 18). The effect of different vehicles of ^{14}C was highly specific and the results are discussed with reference to the ability of purines and other substances to stimulate biosynthesis of riboflavin.—A. M. Copping.

SVOBODOVÁ, S., HÁIS, J. M. and KOŠTĚ, J. V. Vliv pH a světla na riboflavinové roztoky. [The influence of pH and light on riboflavin solutions.] *Chem. listy*, 1953, 47, 205-212. [Biochem. Inst., Fac. Nat. Sci., Karl's Univ., Prague.]

The decomposition of riboflavin (6:7-dimethyl-9-(D-1'-ribityl)-isocalloxazine) by light was studied by paper chromatography. The main products of photolysis in alkaline solution were lumiflavin (6:7:9-trimethyl-isocalloxazine), lumichrome (6:7-dimethylalloxazine) and the substance 27 CX, which was transformed by photolysis into lumiflavin and lumichrome. Photolysis in acetic acid caused the formation of lumichrome and substance 69 CX from riboflavin. Light converted substance 69 CX to lumichrome.

YAGI, K. Action inhibitrice des pterines sur la décomposition photochimique de la riboflavine dans la peau de *Rana nigromaculata*. [Inhibitory effect of pterins on the photochemical decomposition of riboflavin in the skin of *Rana nigromaculata*.] *C.R. Soc. Biol.*, 1954, 148, 752-753. [Fac. Med., Univ. Nagoya.]

Vol. 25, No. 1

A piece of skin from the back of the frog was exposed for 1 hr. to artificial lighting equivalent to daylight. Paper chromatography of an extract of the skin showed no lumichrome and hence no photochemical decomposition of the riboflavin known to be present in the skin.

In a solution of riboflavin containing 200 μg . of the pterin 2-amino-4-hydroxypteridine-6-carboxylic acid, only half the amount of riboflavin was destroyed that was destroyed in a solution in water alone. The interposition of a solution of the pterin between the light and the riboflavin had no protective effect. It is concluded that pterins in the skin of the frog's back probably prevented the photochemical decomposition of riboflavin.—A. Hepburn.

426

MERKEL, J. R. and NICKERSON, W. J. Riboflavin as a photocatalyst and hydrogen carrier in photochemical reduction. *Biochim. biophys. Acta*, 1954, 14, 303-311. [Inst. Microbiol., Rutgers Univ., New Brunswick, N.J.] French and German summaries.

Experiments are described to show the reversible reduction of riboflavin by visible light in the presence of agents promoting the formation of metal complexes. It is considered that the reaction may be of biological significance in view of the abundance of riboflavin in natural materials and the presence of many natural metal chelators (substances forming metal complexes) which could control light-activated reactions.—V. R. Jackson.

427

DECKER, L. E. and BYERUM, R. U. The relationship between dietary riboflavin concentration and the tissue concentration of riboflavin-containing coenzymes and enzymes. *J. Nutrition*, 1954, 53, 303-315. [Dept. Foods Nutr., Michigan State Coll., East Lansing.]

Concentrations of free riboflavin and of the coenzymes flavin adenine dinucleotide and flavin mononucleotide were estimated in the tissues of rats on a dietary intake of riboflavin varying from 0.1 to 43.1 μg . daily. In general a daily intake of 30 μg . was required to give maximum concentrations of the two coenzymes in all tissues. In the brain their concentration was nearly independent of the riboflavin intake; in the heart greater increases were found with increasing intake, and in the kidneys and liver the coenzyme concentrations were almost doubled when the riboflavin intake was increased from 0.1 to 30 μg . daily.

The enzymic activity of the liver was similarly dependent on the riboflavin intake. Xanthine oxidase activity reached a maximum with an

intake of about 30 μ g. riboflavin daily, but D-amino-acid oxidase activity continued to increase up to an intake of over 60 μ g.—M. B. Richards.

428

ERSHOFF, B. H. Effects of riboflavin deficiency on insulin sensitivity in the rat. *Metabolism*, 1954, 3, 357-363. [Emory W. Thurston Labs., Los Angeles, Calif.]

Of 12 rats fed on a diet deficient in riboflavin, 8 developed coma with a blood sugar value below 20 mg. per cent. and died, on the average, 123 min. after the injection of insulin. The blood sugar of rats fed on a complete diet to appetite or with intake the same as that of the deprived rats fell to a minimum after about 90 hr. There were no deaths, and tests showed that riboflavin did not affect the sugar tolerance of the rats.

Rats deprived of riboflavin were less sensitive to insulin than adrenalectomised rats fed on a complete diet.—A. Hepburn.

429

WHITBY, L. G. Transglucosidation reactions with flavins. *Biochem. J.*, 1954, 57, 390-396. [Dept. Biochem., Univ. Cambridge.]

An enzyme with transglucosidase and possibly glucosidase activity was prepared from rat liver. Optimum production of riboflavinyl glucoside and glucose from maltose and riboflavin was obtained at pH 6.7. α -D-Glucose-1-phosphate inhibited the reaction competitively. There was a steady uptake of oxygen as glucose was oxidised only when the enzyme and notatin were incubated in phosphate buffer with maltose, but not with cellobiose, lactose or α -methyl glucosides. Incubation of synthetically prepared riboflavinyl β -D-glucoside or enzymically prepared riboflavinyl glucoside with the enzyme from liver showed that no riboflavin was formed by breakdown of the synthetic form, and the rate of formation of a substance assumed to be glucosflavin from maltosflavin was less than 5 per cent. of the rate of formation of riboflavin from the enzymically prepared riboflavinyl glucoside.

Flavin glucosides were synthesised by the enzyme from a number of isoalloxazine derivatives in the presence of maltose. Maltose could be replaced in the transglucosidase reaction whereby riboflavinyl glucoside was produced by maltulose or turanose, but not by a number of other sugars.

When riboflavinyl glucoside was shaken in phosphate buffer for 2 days at 20° and 37° C., it was stable, and had solubilities at the 2 temperatures of 2.2 and 3.5 mg. per ml., compared with 0.1 and 0.2 mg. per ml. for riboflavin. It is sug-

gested that the much higher solubility of the glucoside may be of importance in the transport of riboflavin.—V. R. Jackson.

430

FORKEE, B. R. and MORGAN, A. F. Effect of adrenocortical hormone on the riboflavin-deficient rat. *J. Biol. Chem.*, 1954, 209, 303-311. [Dept. Home Econ., Univ. California, Berkeley.]

The effect of deprivation of riboflavin was to reduce glyconeogenesis in rats exposed for 24 hr. to an oxygen tension equivalent to an altitude of 20,000 ft. The tests were made after 1, 3, 5, 8 and 12 weeks of a diet without riboflavin, and the defect of carbohydrate metabolism was not apparent until the fifth week of deprivation. From that time there was a rapid decrease in production of sugar in response to anoxia. Administration of riboflavin or adrenal cortical extract or cortisone before exposure to anoxia restored the glycogenic function completely. Deoxycorticosterone was without effect, and riboflavin given to adrenalectomised rats did not improve their ability to counteract anoxia by increased sugar production. It is suggested that "a riboflavin-containing enzyme may be a necessary link in the trigger mechanism of the pituitary-adrenal system".—A. M. Copping.

431

WEISBURGER, J. H., WEISBURGER, E. K. and MORRIS, H. P. The effect of riboflavin on the metabolism of 2-acetylaminofluorene-9-C¹⁴ in rats. *J. Nat. Cancer Inst.*, 1954, 15, 37-47. [Nat. Cancer Inst., Bethesda, Md.]

A single dose of 9.18 mg. 2-acetylaminofluorene-9-¹⁴C in propylene glycol was given to rats on normal diet, rats which had been deprived of riboflavin for 7 weeks and 2 rats which had received a riboflavin supplement for one week. The animals were killed 36 hr. later and radioactivity was measured in certain organs and tissues. The residual radioactivity in the upper gastrointestinal tract was higher in rats deprived of riboflavin, showing that riboflavin deficiency delayed the absorption of the radio-active material. The distribution of radioactivity in other organs and tissues was similar for all the animals. The deprived animals excreted a greater proportion of water-soluble metabolites and a smaller amount of ether-soluble metabolites than normal animals. The amount of radioactivity bound to tissue proteins was not demonstrably different in normal and deprived animals.—A. M. Copping.

OKA, Y. Studies on hydrolytic enzyme of nicotinamide. 1. Nicotinamidase of beer yeast. 2. Purification of nicotinamidase of beer yeast. *J. Biochem., Tokyo*, 1954, 41, 89-99; 101-106. [Dept. Med. Chem., Fac. Med., Univ. Kyoto.]

1. The amidase of a dried acetone preparation of brewer's yeast, tested by measuring ammonia production in Conway's apparatus, hydrolysed nicotinamide and asparagine but not acetamide or benzamide. Nicotinamidase was separated from asparaginase by autolysing pressed yeast with ethyl acetate. The enzyme was inhibited to a varying extent by Hg, Cu, Fe and Co salts but not by MnCl₂. Cysteine, KCN, iodoacetic acid, sodium fluoride and sodium fluoride hydrofluoride had no apparent effect at the pH optimum of from 7 to 7.5. Very little nicotinamidase was found in liver and kidney, which were rich in asparaginase.

2. Fractionation with 45 per cent. acetone produced considerable concentration of the nicotinamidase activity of yeast, and subsequent adsorption on calcium phosphate gel and elution with phosphate buffer at pH 7 produced a fraction with 15 times the enzyme potency of the starting material.—A. M. Copping.

434

SALMON, W. D. The tryptophan requirement of the rat as affected by niacin and level of dietary nitrogen. *Arch. Biochem. Biophys.*, 1954, 51, 30-41. [Dept. Animal Husb., Agric. Exp. Stat., Alabama Polytech. Inst., Auburn.]

Growing rats were fed for 4 weeks on basal diets containing purified casein supplemented with L-cystine, salts, maize oil, choline chloride, sucrose and all vitamins except nicotinic acid. Additions were made at the expense of the sucrose.

When the diet contained 40 per cent. maize grits, the normal weight gain of 25 g. weekly was achieved with a minimum of 21 per cent. casein in the diet, the total tryptophan content being 0.3 per cent., or with 9 per cent. casein and added

DL-tryptophan to make the total 0.19 per cent., or with from 6 to 9 per cent. casein and 2 mg. per cent. added nicotinic acid. The utilisation of N was much more economical on the last 2 diets. The results showed that added DL-tryptophan was more effective than that contained in casein and that a diet of low casein content could be made adequate for growth if supplemented with nicotinic acid.

When the casein in the diet with maize grits was replaced by 12 per cent. of an acid hydrolysate of casein, normal growth was obtained with 0.2 per cent. of added DL-tryptophan, or with 0.1 per cent. if 2 mg. per cent. of nicotinic acid also was included, in which case the casein hydrolysate could be reduced to 7 per cent. without significantly reducing the rate of weight gain. If the extra tryptophan was omitted, massive doses of nicotinic acid, up to 200 mg. per cent., were of no benefit. Growth on a diet containing 7 per cent. casein and 40 per cent. maize grits was depressed, and utilisation of food and nitrogen reduced, even when 4 mg. per cent. of nicotinic acid was present, if 12 per cent. casein hydrolysate or 11.3 per cent. gelatine was included. To secure normal growth extra tryptophan, 0.1 per cent., was needed, which made the total equal to twice the amount in the basal diet. Similar results were obtained when the maize grits were replaced by 7 per cent. maize gluten meal. Even when the casein was increased to 20 per cent., the total tryptophan content being 0.3 per cent., addition of 10 per cent. gelatine depressed growth unless counteracted by 2 mg. per cent. nicotinic acid. The action of added glycine, from 2.6 to 5 per cent., was similar to that of gelatine. In a diet containing 9 per cent. casein but no maize grits, casein hydrolysate, from 2 to 12 per cent., depressed still further the subnormal growth; inclusion of 2 mg. per cent. nicotinic acid improved matters, but extra tryptophan was needed to secure normal weight gain and good utilisation of food and N.

It is concluded that the requirement of the rat for tryptophan is not constant. With adequate nicotinic acid in the diet the requirement at a dietary protein level of 10.8 per cent. was 0.13 per cent. and in absence of nicotinic acid 0.19 per cent. With a protein, casein, level of about 20 per cent. without nicotinic acid, the requirement was 0.3 per cent. Tryptophan-deficient protein or protein hydrolysate, even in presence of excess nicotinic acid, consistently depressed growth; the effect could be corrected by adding DL-tryptophan. The effect of such tryptophan-deficient materials was to reduce utilisation of tryptophan and thus to increase the requirement.—H. Chick.

435

SUBRAHMANYAM, K. **Tryptophane-sparing effect of nicotinic acid.** *Indian J. Med. Res.*, 1954, **42**, 211-214. [Sriram Chandra Bhanj Med. Coll., Cuttack.]

The effect of nicotinic acid on tryptophan requirement was studied in N balance experiments with rats given a basal diet of low tryptophan content, alone or with supplements of tryptophan with or without nicotinic acid. The biological value of protein low in tryptophan was enhanced by additional tryptophan and with a small supplement the effect was further increased by giving nicotinic acid. With adequate addition of tryptophan, nicotinic acid had no further effect. The interrelation of tryptophan and nicotinic acid metabolism is briefly discussed.—A. M. Copping.

436

GHOSH, N. C., CHATTERJEE, K., CHATTOPADHYAY, D. P. and BANERJEE, S. **Liver as the site of synthesis of nicotinic acid from tryptophan in rats.** *Proc. Soc. Exp. Biol. Med.*, 1954, **86**, 346-347. [Dept. Physiol., Presidency Coll., Calcutta.]

Rats, of bodyweight 125 to 175 g., fed for one week on a basal diet deficient in nicotinic acid but containing 1 per cent. DL-tryptophan, received by intraperitoneal injection 0.03 ml. carbon tetrachloride per kg. bodyweight, daily for one week. Estimation in 24-hr. samples of urine of nicotinic acid, quinolinic acid and N-methylnicotinamide showed a great reduction in the amount of them after the injections, the respective values in g. falling from 50 to 29, 474 to 117 and 603 to 187.

Livers were homogenised immediately after death from two groups of rats on the same basal diet, of which one group had received injections of carbon tetrachloride for 7 days. Nicotinic acid and quinolinic acid were estimated in portions of the liver from both groups, before and after 30 minutes' incubation with DL-tryptophan, 10 mg. in 5 ml. of a suitably buffered solution. The results showed that the livers from neither group could convert tryptophan to nicotinic acid, but that the livers from the normal rats could convert it to quinolinic acid more efficiently than the livers damaged with carbon tetrachloride.

It is suggested that the liver is the principal site for synthesis of nicotinic acid from tryptophan.

FRIED, R. and CARVALHO DA SILVA, A. **Some effects of nicotinamide, diammonium citrate and urea as supplements to low-protein diets.**

Effects of nicotinamide and nitrogen supplements in low-protein diets containing sulfonamides. *Internat. Ztschr. Vitaminforsch.*, 1954, **25**, 281-294; 295-302. [Dept. Physiol., Sch.

Med., Univ. São Paulo, Brazil.] French and German summaries.

The first paper describes the growth of weanling rats on purified diets containing 8 per cent. casein. Supplements of urea or of diammonium citrate, of nitrogen content equivalent to 10 per cent. protein, were added to the diet of some groups. In some, nicotinamide was given alone or with one of the non-protein nitrogen supplements. Both urea and diammonium citrate produced good growth in the presence of nicotinamide and both tended to be toxic if given without nicotinamide. The diammonium citrate was more toxic than urea. Nicotinamide alone caused some improvement of growth on the low-protein diet. When the casein content of the diet was reduced to 6, 4 or 2 per cent., nicotinamide increased the growth rate or prevented loss of weight and death. Urea and diammonium together permitted growth with very low intakes of casein.

Studies were made also of weight recovery after 23 or 27 days of protein depletion on a diet with 8 per cent. casein, and again nicotinamide alone or combined with urea was an effective supplement. Diammonium citrate did not permit weight recovery.

The xanthine oxidase activity of the liver reflects protein utilisation, so the activity of this enzyme was measured in the livers of rats from some of the experiments. Nicotinamide, urea and small amounts of diammonium citrate in the diet stimulated xanthine oxidase activity; the most marked activity occurred in livers from rats given nicotinamide and urea.

Tests with weanling mice showed growth responses to nicotinamide and urea similar to those of rats. Supplements of urea or diammonium citrate given alone depressed the growth of mice.

In the second paper the effects are reported of some insoluble sulphonamides on rats having diets with 8 per cent. casein and supplements of urea or diammonium citrate with or without nicotinamide. Sulphasuxidine proved more toxic than sulphathalidine incorporated as 2 per cent. of the diet, and the toxicity of the sulphasuxidine was less easily counteracted by nicotinamide and urea. A supplement of nicotinamide or urea given separately was not protective against the effects of sulphasuxidine. With sulphathalidine nicotinamide alone improved growth. The problem of the toxicity of sulphonamides with low-protein diets is discussed.—A. M. Copping.

FLYNN, L. M., ZUBER, M. S., LEWEKE, D. H., GRAINGER, R. B. and HOGAN, A. G. **Relation between protein content of corn and concentration of amino acids and nicotinic acid.** *Cereal Chem.*, 1954, **31**, 217-228. [Dept. Agric. Chem., Univ. Missouri, Columbia.]

Tryptophan, lysine, methionine and nicotinic acid were estimated microbiologically, and cystine chemically, in hydrolysates of the kernels of Jumbo Yellow Dent maize of varying protein content.

Whole dry maize of low protein content contained on the average 9.9 per cent. crude protein and that of high protein content 14.3 per cent. Contents in mg. per 100 g. dry matter in low-protein maize were tryptophan 87, lysine 314, methionine 199, cystine 144 and nicotinic acid 2.53. Corresponding values for high-protein maize were 99, 380, 239, 182 and 2.40. The amount per g. protein of each of the nutrients decreased as the protein content increased, though the changes in sulphur-containing amino-acids were slight.

As the percentage of crude protein increased, the proportion of zein in the protein increased also, causing a decrease in the concentration of the essential nutrients tryptophan and lysine, which, it is thought, should be taken into account when protein yields are increased heavily by use of fertilisers.—V. R. Jackson.

TEAS, H. J., TEAS, A. N. and CAMERON, J. W. **Niacin relationships in developing and mature maize endosperms of brittle and related genotypes.** *Cereal Chem.*, 1954, **31**, 250-256. [U.S. Dept. Agric., Fed. Exp. Stat., Mayaguez, Puerto Rico.]

Two mutant recessive genotypes of brittle-type maize were studied. The kernels were similar in appearance, with their colour darker than normal, and a degree of wrinkling and transparency intermediate between sugary and normal types. The endosperms had 46 and 66 per cent. of normal weight. Nicotinic acid was estimated in the kernels and in normal kernels at intervals of from 14 to 46 days after pollination. In one of the 2 types, after 14 days, there was a slight but significant difference in nicotinic acid content from the normal and after 21 days no difference. After 25 days and subsequently the mutant had a content higher than normal. In the other type, the differences from normal were significant from 14 days

on. Both the brittle types had the higher nicotinic acid content which increased rapidly from 14 to mid-development after 39 days, and then decreased. The differences were larger on a dry weight basis than for individual endosperms, as the dry weight of the endosperms was considerably below normal from 25 days on.

Kernels showing both recessive sugary and brittle characters contained no more nicotinic acid than sugary kernels from the same ear, but on a weight basis their content was twice as high, giving the greatest value yet recorded for nicotinic acid in maize kernels.—V. R. Jackson.

BRESSANI, R., MARCUCCI, E., ROBLES, C. E. and SCRIMSHAW, N. S. **Nutritive value of Central American beans. 1. Variation in the nitrogen, tryptophane, and niacin content of ten Guatemalan black beans (*Phaseolus vulgaris*, L.), and the retention of the niacin after cooking.** *Food Res.*, 1954, **19**, 263-268. [Inst. Nutric. Centro América y Panamá, Guatemala.]

Ten samples of black beans, *Phaseolus vulgaris*, from the 1950 autumn crop were obtained in different regions of Guatemala. Estimation was made in September 1951 of N, tryptophan and nicotinic acid in the beans raw and boiled for 3½ hr. at 96°C.

The percentage of moisture ranged from 5.1 to 11.1, average 8. On a 10 per cent. moisture basis, the percentage of N ranged from 2.92 to 3.64, corresponding to 18.3 and 22.8 per cent. protein. The differences in protein content between varieties were highly significant. The percentage of tryptophan ranged from 0.13 to 0.19, average 0.17, and was not related to variations in the N content. The nicotinic acid content ranged from 2.14 to 2.53, average 2.42, mg. per 100 g., and the values tended to vary with the tryptophan but not with the N content. Differences in vitamin content between varieties were significant.

The percentage retention of nicotinic acid in the cooked beans ranged from 84.2 to 95.1, average 88.5. The average percentage of moisture after cooking was 76.3. Differences in vitamin content were greater than between raw samples.

It is estimated that the Guatemalan Indian diet of maize and black beans provides 0.36 g. tryptophan and nearly 8 mg. nicotinic acid daily, which may explain the absence of pellagra from Central America, where the popular diet contains large quantities of maize.—V. R. Jackson.

442

ROHRLICH, M. **Die Nicotinsäure im reifenden Sauermilchkäse. [Nicotinic acid in ripening sour milk cheese.]** *Ztschr. Lebensmittel-Untersuch. Forsch.*, 1954, **99**, 109-117.

In view of the known importance of nicotinic acid in the metabolism of lactobacilli, the occurrence of the vitamin in milk curd during ripening was investigated. During 8 days there was an increase in total nicotinic acid in the curd from an original value of about 6 to about 20 μg . per g. in the fully ripe sour milk cheese. The content of the crust was always greater than of the curd. If ripening was hastened by raising the temperature of the cheese room to from 22° to 24° C., the nicotinic acid content of the curd was higher than at the usual temperature of from 16° to 17° C. The high concentration in the crust was associated with

the growth of yeasts which were shown to be capable of synthesising nicotinic acid. In the later stages of ripening an increase of lactobacilli and other organisms occurred and was associated with the development of the typical flavour of the cheese. It is considered probable that the nicotinic acid synthesised by the yeasts in the crust was important for the growth of the other organisms in the centre of the cheese. The acidity of the curd was shown to influence the distribution of nicotinic acid between the crust and the centre of the ripened cheese.—A. M. Copping.

BUTLER, L. C. and MORGAN, A. F. Weight, ascorbic acid and cholesterol changes in adrenals of pyridoxine-deficient adult male rat. *Proc. Soc. Exp. Biol. Med.*, 1954, **86**, 264-266. [Dept. Home Econ., Univ. California, Berkeley.]

The functional capacity of the adrenal glands of rats deprived of vitamin B₆ was measured by their response to adrenocorticotrophic hormone after removal of the pituitary gland, and by the response of intact animals to low oxygen tension. In hypophysectomised rats deprivation of vitamin B₆ did not arrest the removal of ascorbic acid or the increase of adrenal gland weight in response to the hormone. There was no change in the cholesterol content of the adrenal glands. At low oxygen tension, normal intact animals showed characteristic loss of adrenal cholesterol, but rats deprived of vitamin B₆ did not do so, and the weight and ascorbic acid content of the adrenal glands were maintained.—A. M. Copping.

BEATON, J. R. and GOODWIN, M. E. Thyroid feeding and vitamin B₆ deprivation in the rat. *Proc. Soc. Exp. Biol. Med.*, 1954, **86**, 426-428. [Dept. Pub. Health Nutrit., Univ. Toronto.]

Previous studies (Abst. 3053, Vol. 24) showed that neither thyroidectomy nor administration of thiouracil altered the vitamin B₆ deficiency syndrome. The effect of giving 1 mg. desiccated thyroid per g. diet was investigated with rats weighing about 100 g., given a purified diet with or without vitamin B₆. Thyroid feeding was continued for 21 days and, although it further reduced the weight gain of rats deprived of vitamin B₆, it did not alter the Hb concentration, packed cell volume or amino-N of the blood. It reduced the high value for blood urea of deprived rats, but it had no demonstrable effect on the development of skin lesions or other signs of vitamin B₆ deficiency.

BRAUNSHTEIN, A. E. and SHEMYAKIN, M. M. Teoriya protsessov aminokislotoznogo obmena, kataliziruemykh piridoksalevymi enzimami. [Theory of the process of amino-acid metabolism, catalysed by pyridoxal enzymes.] *Biokhimiya*, 1953, **18**, 393-411. [Inst. Biol. Khim., Akad. Med. Nauk SSSR.]

A detailed account is given of a theory advanced earlier (see Abst. 4277, Vol. 23), according to which reactions involving amino-acids that are catalysed by phosphopyridoxal enzymes can be explained by the capacity of the aldehyde group of the phosphopyridoxal-protein to interact with the amino

groups of the amino-acids to form the respective azomethines (Schiff bases). In the azomethines, redistribution of the electron density may occur such that the character of carbon atom 1 is changed. The electron density on this atom should be less than on the α -carbon atom of the original amino-acid, which accounts for the difference in the character of these carbon atoms. It is because of the difference in electron density that the azomethine formed can undergo reactions which the original amino-acid could not. Some of these reactions are, no doubt, related to changes in the hydrogen atom and in electron density on atoms 1, 3, 5, 7 and 9 in the anion formed; tautomeric forms of the azomethines are possible which are N-substituted α -amino-acids. Hence in their chemical character the azomethines are nearer to the α -keto-acids than to the original α -amino-acids, and therefore react more like the keto-acids. The type of conversion which any given amino-acid undergoes depends on the nature of the protein moiety of the enzyme and on the structure of the amino-acid concerned. The theory is applied to illustrative reactions.—W. Hughes.

BEREZOV, T. T. Rol' vitamina B₆ v obmene L- i D-aminokislot v organizme zhivotnykh. Vliyane B₆-avitaminoza na prizhiznennye prevrashcheniya L- i D-fenilalanina u kryss. [The role of vitamin B₆ in the interchange of L- and D-amino-acids in animal organisms. The influence of vitamin B₆ deficiency on the transformation of L- and D-phenylalanine in living rats.] *Dokl. Akad. Nauk S.S.S.R.*, 1952, **86**, 605-608. [Inst. Biol. Khim., Akad. Med. Nauk SSSR.]

The urine of 4 rats deprived of vitamin B₆ and of 4 non-deprived rats was analysed for total N, urea, ammonia, amino- and peptide N, and undetermined N calculated by difference, before and after oral administration of L- or D-phenylalanine. Before administration of L- or D-phenylalanine, urea N was significantly less in the deprived animals than in the non-deprived, and undetermined N was correspondingly higher; the values for ammonia, amino- and peptide N were normal. In deprived animals as soon as L- or D-phenylalanine was given, retention of N occurred, and when the amount was increased total urine N was somewhat less even than before the amino-acid was given, which is regarded as a manifestation of enhanced phenylalanine toxicity during vitamin B₆ deficiency.

Administration of phenylalanine, particularly the D-form, led to a slight increase in excretion of peptide and amino-N. L-Phenylalanine gave a further strong decrease in urea, both absolute and relative, and a corresponding increase in undetermined N. On the other hand, on giving D-

phenylalanine, excretion of urea by test rats increased and there was a sharp decrease in undetermined N. In comparison with non-deprived rats, when L-phenylalanine was given, the total aromatic products increased from 3.5 to 4 times, primarily at the expense of phenolic acids. There was only an insignificant increase on giving the D-form, and there was a sharp increase in excretion of phenylpyruvic acid balanced by reduced excretion of hydroxy-aromatic products. The results are in harmony with the assumption that the decomposition of L-phenylalanine and its formation from phenylpyruvic acid in the rat organism proceed by transamination.—W. Hughes.

450

BEREZOV, T. T. Vliyane B₆-avitaminoza na prizhiznennye prevrashcheniya L- i D-triptofana. [Influence of vitamin B₆ deficiency on changes of L- and D-tryptophan *in vivo*.] *Dokl. Akad. Nauk S.S.S.R.*, 1953, **90**, 623-626. [Inst. Biol. Khim., Akad. Med. Nauk SSSR.]

Four rats deprived of vitamin B₆ and 4 not deprived were given from 1.7 to 4 m.mol. of L- or D-tryptophan by mouth. Before and after administration, N fractions, α -keto-acids, tryptophan, kynurenine and xanthurenic acid were estimated in the urine. Tryptophan and its cyclic metabolic products in the urine were investigated also by paper chromatography. From his results the author concluded that transamination occurs in the synthesis of L-tryptophan from keto-acid (indolepyruvic acid) and in the formation of urea from the amino group of L-tryptophan, directly or after conversion of L-tryptophan into L-kynurenine or L-alanine. In accordance with the concept of "indirect" mechanisms for urea formation and deamination of L-amino acids, L-tryptophan behaves like L-phenylalanine in deficiency of vitamin B₆ (see previous Abst.); it is not used for urea synthesis and is consequently not deaminated. The amino group of D-tryptophan is split off by D-amino-acid oxidase, and in vitamin B₆ deficiency goes directly into urea. But, just as when D-phenylalanine is given to rats deprived of vitamin B₆, breakdown of transamination hinders the conversion of the α -keto-acid formed into the L-amino-acid (i.e., inversion of D-tryptophan), and this leads to excretion of large amounts of indolepyruvic acid and unused D-tryptophan.

The formation of D-kynurenine from D-tryptophan as found by Kotake was not observed in the present experiments.—W. Hughes.

451

BEREZOV, T. T. Vliyane B₆-avitaminoza na obmen L-glyutaminovoi i L-asparaginovoi kislot, glitsina i uksusnokislologo ammoniya v

organizme krysy. [Effect of vitamin B₆ deficiency on metabolism of L-glutamic and L-aspartic acids, glycine and ammonium acetate in the rat organism.] *Dokl. Akad. Nauk S.S.S.R.*, 1953, 90, 1087-1090. [Inst. Biol. Khim., Akad. Med. Nauk SSSR.]

Experiments on rats deprived of vitamin B₆ showed that the N of L-aspartic acid and ammonia was freely changed to urea, but the synthesis of urea from L-glutamic acid was severely disrupted. The formation of urea from glycine was not affected. The author concludes, therefore, that transamination probably does not play an essential part in the disappearance of glycine. The decrease of urea formation in vitamin B₆ deficiency is, therefore, not caused by a breakdown in one of the stages of the ornithine cycle. The N of those acids which are deaminated without the participation of vitamin B₆ enzymes, such as D-acids oxidised by D-amino-acid oxidase, and of certain L-amino-acids, is easily converted by way of ammonia into urea during vitamin B₆ deficiency. The cessation of urea formation from L-glutamic acid indicates that glutamic acid can proceed to urea only by way of aspartic acid, that is to say, by transamination. It follows further that deamination of glutamic acid in the liver and other organs by active glutamic dehydrase, with the participation of the coenzyme, does not play an essential part in the catabolism of L-glutamic acid in the rat organism.—W. Hughes.

452

GORYACHENKOVA, E. V., VOLOVNIK, B. Ya. and ZAIDEL'MAN, F. R. Vliyaniye nedostatochnosti vitamina B₆ na obrazovanie merkapturovoi kisloty i na peresul'pirovanie v organizme krysy. [The effect of vitamin B₆ deficiency on the formation of mercapturic acid and on sulphur transfer in the rat organism.] *Dokl. Akad. Nauk S.S.S.R.*, 1953, 93, 111-114. [Inst. Biol. Khim., Akad. Med. Nauk SSSR.]

It was established in tests on normal rats and rats deprived of vitamin B₆ that, after administration of bromobenzene, additional excretion of mercapturic acid for a 24-hr. period during which DL-methionine was administered was almost the same for both sets of animals. No difference was found between the 2 groups in the amount of radio-active S transferred from labelled methionine to the mercapturic acid excreted. There was also no difference in the amount of radio-active S transferred from the methionine to the cysteine of the proteins from internal organs when the rats were killed 24 hr. after they had been given methionine. When the experimental time was reduced to 4 or 6 hr., and an additional amount of unlabelled methionine was given in addition to the ³⁵S-methionine, less radio-active S was transferred

from methionine to the cysteine of protein from the liver and other organs in the rats deprived of vitamin B₆.—W. Hughes.

453

GORYACHENKOVA, E. V. Aktivnost' fermentnoi sistemy peresul'firovaniya v razlichnykh organakh krysy v norme i pri B₆-avitaminoze. [The activity of the sulphur-transfer enzyme system in organs of rats kept in normal conditions and deprived of vitamin B₆.] *Dokl. Akad. Nauk S.S.S.R.*, 1953, 93, 319-320. [Inst. Biol. Khim., Akad. Med. Nauk SSSR.]

It was shown experimentally, in the present work, that transfer of S (see Abst. 458, Vol. 22) could occur in healthy rats not only in the liver but also in the spleen, kidney and heart, in that order of activity, but did not occur in brain tissue or in skeletal muscle. In deficiency of vitamin B₆, transfer of S was greatly disturbed; it disappeared completely from the heart and almost completely from the liver; in the kidneys and spleen transfer of S was reduced by from 30 to 40 per cent. but still remained at a fairly high level.—W. Hughes.

454

BEATON, J. R., GOODWIN, M. E., OZAWA, G. and MCHENRY, E. W. The effects of vitamin B₆ and deoxyypyridoxine on urea formation in rats. *Arch. Biochem. Biophys.*, 1954, 51, 94-101. [Dept. Pub. Health Nutrit., Sch. Hyg., Univ. Toronto.]

The formation of urea in liver slices was increased in rats deprived of vitamin B₆ but not significantly in rats given the antivitamin deoxyypyridoxine, which increased the external signs of deficiency. The increase in urea was probably mediated through the ornithine cycle, as liver arginase activity was similarly increased by deprivation of vitamin B₆. The ratio of blood urea to arginase activity was constant in the presence or absence of vitamin B₆. Deoxyypyridoxine decreased the arginase activity in vitamin-B₆-depleted rats.

The failure of deoxyypyridoxine to accentuate the abnormal N metabolism produced by deficiency of vitamin B₆ seemed to favour the absence of any direct relation between N metabolism and the external signs of vitamin B₆ deficiency.

7. Since xanthurenic acid was found to be a diabetogenic substance occurring naturally in the organism, some agency was sought which might counteract it.

When the liver or kidney tissue of rat or rabbit was incubated with xanthurenic acid and phosphate buffer at pH 7.0, the xanthurenic acid progressively disappeared. The conditions most favourable to the destruction were studied with rabbit liver. The most favourable pH and temperature were 7.2 and 38° C. Activity was destroyed at 80° C., and was considerably inhibited by KCN, NaF and moniodoacetic acid, in suitable concentration. On fractionation with saturated ammonium sulphate, the activity went with the globulin fraction. The activity was adsorbed on kaolin and eluted with sodium carbonate. The active agent is presumed to be an enzyme and is called xanthurenicase. After disappearance of xanthurenic acid through the activity of the enzyme, hydrolysis did not restore it, and an unidentified spot appeared on paper chromatography. The extraction liquid of the spot, presumed to represent a decomposition product of xanthurenic acid, was tested spectrophotometrically and had a maximum of absorption at 276 mμ.

8. Xanthurenic acid and total acetone bodies were estimated in the urine of rats weighing from

150 to 200 g., fed on a diet high in fat or on one low in vitamin B₆.

In rats [presumably fed on normal diet] 50 mg. per kg. bodyweight xanthurenic acid were injected every other day for many weeks. The total acetone bodies in the urine progressively increased till the value reached 7 times the initial one. When the rats thus injected were fed on either of the 2 experimental diets, acetone bodies increased to 10 times the initial value.

Rats were given for 3 days 0.4 g. daily of Na butyrate with and without daily injection of 1 mg. anthranilic acid. With the butyrate alone, the total acetone bodies increased greatly, but to only half that extent if anthranilic acid was given as well. In a similar experiment 2 mg. pyridoxine had the same effect.

Excretion of xanthurenic acid in the urine after administration of 100 mg. tryptophan was greatly increased when 1500 mg. acetoacetic acid were given as well. Smaller and larger amounts had less effect.—E. M. Hume.

HASSINEN, J. B., DURBIN, G. T. and BERNHART, F. W. The vitamin B₆ content of milk products. *J. Nutrition*, 1954, **53**, 249-257. [Res. Development Dept., Nutrit. Div., Wyeth Laboratories, Inc., Mason, Mich.]

Vitamin B₆ was estimated with *Saccharomyces carlsbergensis* in fresh milk and milk products. It was found that the heat used to sterilise liquid products caused a considerable decrease in vitamin B₆ potency which progressed for as long as 7 days after the initial heating. Added pyridoxine was more resistant to heat treatment of milk products than pyridoxal, pyridoxamine, or the form of the vitamin occurring naturally in the milk. Liquid products contained from 33 to 64 per cent. of the vitamin in the fresh milk, dried ones from 69 to 89 per cent.—A. M. Copping.

LEFEBVRES, J. Influence d'une déficience pantothenique légère sur les résultats de la gestation chez la ratte. [Effect of slight pantothenic acid deficiency on the results of gestation in the rat.] *C.R. Acad. Sci.*, 1954, **238**, 2123-2125.

Vol. 25, No. 1

For from 3 to 11 days before mating and throughout gestation rats were given a basal synthetic diet without pantothenic acid, alone or with 10, 20 to 25, 30 to 35, 40 to 45 or 50 μg. pantothenic acid daily. The number of resorptions and of abnormal and normal foetuses was recorded.

With less than 10 μg. daily all the foetuses were resorbed; above that amount the number of resorptions decreased as the amount of pantothenic acid increased. The largest number of abnormal foetuses occurred with 20 μg.; for completely normal development 50 μg. was the minimum amount.—V. R. Jackson.

460

GUGGENHEIM, K. Studies on water metabolism of pyridoxine and pantothenic acid deficient rats. *Endocrinology*, 1954, 55, 156-162. [Lab. Nutrit., Dept. Biochem., Hadassah Med. Sch., Hebrew Univ., Jerusalem.]

Rats given purified diets lacking pyridoxine or pantothenic acid exhibited a delayed diuretic response to a water load. Their response to injection of pitressin was, however, similar to that of normal rats, which suggested that the delayed diuresis was not due to failure of the liver to inactivate the antidiuretic hormone (cf. Abst. 4755, Vol. 23). The role of adrenal cortical hormones was then examined. None of them had any effect on diuresis in normal rats, but cortisone or adrenocorticotrophic hormone increased excretion of water in rats deprived of pyridoxine and pantothenic acid.—A. M. Copping.

461

KOCH, R. Der Einfluss der Pantothensäure auf die adrenaletomierte Ratte. [Effect of pantothenic acid on the adrenaletomized rat.] *Arch. exp. Pathol. Pharmacol.*, 1954, 221, 460-465. [Radiol. Inst., Univ. Freiburg i. Br.]

Administration of 20 or 50 mg. pantothenic acid by intramuscular injection or by stomach tube did not prolong the survival time of adrenaletomized rats already receiving adequate pantothenic acid. The effect was the same with animals on a mixed diet of oats, meat and shrimps with a mash twice weekly of baker's yeast, wheatmeal and cod liver oil, or a diet of palm oil, wheat flour, dried skimmed milk, salt mixture, yeast and cod liver oil and a comprehensive vitamin supplement. After the operation the rats had 1 per cent. NaCl to drink, and additional saline given by stomach tube did not appear to increase the survival time. The

results are discussed with reference to those of Ralli and co-workers who during the past 10 years have claimed that extra pantothenic acid and NaCl prolong the life of adrenaletomized rats (see Abst. 4346, Vol. 18).—A. M. Copping.

ARTOM, C. Effects of pantothenic acid and its analogs in radiation injury by P^{32} . *Proc. Soc. Exp. Biol. Med.*, 1954, 86, 162-165. [Dept. Biochem., Bowman Gray Sch. Med., Wake Forest Coll., Winston-Salem, N.C.]

In continuation of studies on the effect of dietary protein and vitamin B complex in modifying the damage due to ^{32}P in mice, pantothenic acid derivatives were given to mice with a diet deficient in pantothenate (cf. Absts. 2333, Vol. 20; 1885, Vol. 21; 1967, Vol. 22). Considerable protection against injury from ^{32}P was given by injection of Ca pantothenate or of pantoyltaurine, and slight protection by injection of taurine. No effect was shown with co-methyl pantothenate.

BIOTIN

465

WRIGHT, L. D. and CRESSON, E. L. Biotin *l*-sulfoxide. 1. The occurrence of a previously unrecognized form of biotin in certain fermentation sources.

WRIGHT, L. D., CRESSON, E. L., VALIANT, J., WOLF, D. E. and FOLKERS, K. 2. The isolation of a crystalline factor with biotin activity from *Aspergillus niger* culture filtrates. 3. The characterization of biotin *l*-sulfoxide from a microbiological source. *J. Amer. Chem. Soc.*, 1954, 76, 4156-4160; 4160-4163; 4163-4166. [Sharpe and Dohme Div., Merck and Co., Inc., West Point, Pa.]

1. On addition of pimelic acid to a culture of *Aspergillus niger* a substance appeared with the

activity of biotin as shown by tests with *Neurospora crassa*. Paper bio-autographs showed the substance to be distinct from biotin and desthiobiotin but similar to biocytin. Several species of penicillium synthesised the same substance from pimelic acid.

2. From a large volume of medium in which *A. niger* had been given, the unknown substance was crystallised from aqueous acetone after a procedure involving adsorption on charcoal, elution with alcoholic NH_3 , chromatography on Superfilitrol-Celite, alumina and ion exchange columns, and counter-current distribution between butanol and water.

3. Chemical and microbiological comparison of the unknown substance with an authentic

N.A. and B., January 1955

sample showed it to be biotin *l*-sulphoxide. It appeared to originate by enzymic reaction and not from atmospheric oxidation.—A. Hepburn.

466

MELVILLE, D. B., GENGHOFF, D. S. and LEE, J. M. **Biological properties of biotin *d*- and *l*-sulfoxides.** *J. Biol. Chem.*, 1954, 208, 503-512. [Dept. Biochem., Cornell Univ. Med. Coll., New York.]

Biotin sulphoxides, obtained as intermediate oxidation products between biotin and its sulphone,

were tested for their growth effects on *Saccharomyces cerevisiae*, *Lactobacillus casei* and *L. arabinosus*. They had very varying activity for the 3 organisms, but were never inhibitory like biotin sulphone. They had no curative effect on biotin deficiency in rats, even in very large doses. Chromatographic analysis showed that the sulphoxides were partly converted to biotin during their utilisation by micro-organisms. The sulphoxides were capable of combining with avidin.

475

BÍLEK, O. Kvantitativní působení pterinů na vly obraz krevní. [Quantitative influence of pterins on the white blood picture.] *Lékařské listy*, 1954, 9, 348-352. [Inst. Gen. Exp. Pathol., Masaryk Univ., Brno.] English, French and Russian summaries.

Of 7 groups of 10 leucaemic mice, one received aminopterin, produced in the laboratory, in a curative dose; 5 received one-tenth, twice, 5 times, 10 times or 100 times the curative dose. In the seventh group the mice received daily at first the curative dose and after 16 days, when the white blood count increased and the animals became resistant to aminopterin, the daily dose was doubled and after a further 8 days trebled. Treatment was followed first by a fall and then by a rise of the leucocyte count, showing the develop-

ment of resistance to aminopterin which yielded and developed again as the amount given was raised even in the same animals. It is supposed that after a time the organism forms a generation of cells that are resistant to aminopterin.

477

GOLDIN, A., MANTEL, N., GREENHOUSE, S. W., VENDITTI, J. M. and HUMPHREYS, S. R. Factors influencing the specificity of action of an antileukemic agent (aminopterin). Time of treatment and dosage schedule. *Cancer Res.*, 1954, 14, 311-314. [Lab. Chem. Pharmacol., Nat. Cancer Inst., Bethesda, Md.]

Aminopterin was administered in one or several doses to mice with leucaemic tumours at different intervals after implantation of the tumour. A single dose had the maximum effect in increasing survival time when administered from 3 to 4 days after implantation. Toxicity of the drug for the host was constant within the first 6 days; the results, therefore, showed that the drug had an increased effect on the tumour when given after from 3 to 4 days. Of the treatments with multiple doses, those after 2 and 4 days, and after 2, 4, and 6 days, had greater antileucaemic effect than a single dose, without greatly increasing the total toxicity to the host.

The results are examined statistically.

DE RENZO, E. C. and DESSAU, F. I. Prevention of bone-marrow aplasia induced by aminopterin with folacin and folic acid. *Proc. Soc. Exp. Biol. Med.*, 1954, 86, 231-233. [Chem. Biol. Res. Sect., Lederle Labs. Div., Amer. Cyanamid Co., Pearl River, N.Y.]

Bone marrow aplasia was induced by feeding weanling albino rats on a purified diet and giving by mouth 10 µg. aminopterin daily for 5 days. Some rats received from 20 µg. to 5 mg. folic acid or from 10 to 150 µg. folic acid daily at the same

N.A. and R., January 1955

time as the aminopterin. A system was evolved for assessing the extent of the bone marrow changes by which it was found that the protection given by the doses of 150 µg. folic acid was complete and of 5 mg. folic acid almost complete. Smaller doses of folic or folinic acid had less effect. Simultaneous administration of ascorbic acid or vitamin B₁₂ did not increase the protective effect of folic acid.—A. M. Copping.

479

VITALE, J. J., ZAMCHECK, N., DiGEORGIO, J. and HEGSTED, D. M. Effects of aminopterin administration on the respiration and morphology of the gastrointestinal mucosa of rats. *J. Lab. Clin. Med.*, 1954, 43, 583-594. [Mallory Inst. Pathol., Boston City Hosp., Mass.]

Adult female rats received a basal synthetic diet containing 18 or 60 per cent. protein supplemented with B vitamins in adequate amounts, alone or with daily subcutaneous injections of aminopterin, 60, 120 or 240 µg. per kg. bodyweight. The animals were killed and the tips of some duodenal villi were removed for manometric estimation of oxygen uptake. The rest of the intestine was examined histologically.

Survival time was roughly in inverse proportion to the dose of aminopterin, 9 days for 120 µg. per kg. and twice as long for half that dose. High protein did not have a protective effect but when to high protein 0.3 per cent. cystine was added, there was some effect. All animals receiving

aminopterin had a rough coat and watery diarrhoea, and the gastro-intestinal tract contained blood.

In the duodenal mucosa from animals receiving no aminopterin the oxygen uptake fell by 65 per cent. 24 hr. after administration of 240 µg. aminopterin per kg. bodyweight and 48 hr. after 120 µg. Respiration often returned to normal after 4 days even when the drug was continued. After a single dose of 480 µg. per kg. bodyweight, values fell rapidly but were normal after 48 hr.

Morphological changes occurred less rapidly than metabolic changes. They included reduction in the number of mitotic figures in the crypts of Lieberkühn, followed by cellular necrosis. At this stage the epithelium of the villus tips was not greatly affected; their rate of respiration corresponded with the rate of mitosis in the crypts. In animals killed just before death, the *tunica propria* of the villus was infiltrated with leucocytes; in advanced lesions there was degeneration of the villus tip with loss of epithelium and haemorrhage.

VITAMIN B₁₂

481

LILLIE, R. J., BIRD, H. R., SIZEMORE, J. R., KELLOGG, W. L. and DENTON, C. A. Assay of feedstuffs and concentrates for vitamin B₁₂ potency. *Poultry Sci.*, 1954, 33, 686-691. [Bur. Animal Indust., U.S. Dept. Agric., Beltsville, Md.]

The vitamin B₁₂ potency of feeds and commercial vitamin B₁₂ concentrates used in poultry feeding were compared by a standard microbiological method and by a biological method with chicks. The results obtained by the two methods were similar for some sewage sludges, defatted liver substance, crabmeal, fishmeal, poultry viscera meal, dried skimmed milk and dried whey. With other sludge preparations, fish solubles, meatmeal, egg yolk and some vitamin B₁₂ concentrates the results were widely divergent. In general where the results were divergent, the value obtained with chicks was the higher, and the problem of unidentified growth factors is discussed. None of the food materials examined except some sludges contained more than 1 µg. vitamin B₁₂ per g., and

it is, therefore, suggested that commercial vitamin B₁₂ concentrates of higher potency may have value in poultry feeding.—A. M. Copping.

482

SHENOY, K. G. and RAMASARMA, G. B. Extraction procedure and determination of the vitamin B₁₂ content of some animal livers. *Arch. Biochem. Biophys.*, 1954, 51, 371-378. [Res. Control Div., Raptakos, Brett and Co., Ltd., Bombay.]

A turbidimetric modification of the U.S.P. XIV microbiological method for estimating vitamin B₁₂ was used with *Lactobacillus leichmannii* as the test organism. The most satisfactory release of vitamin B₁₂ from liver samples was obtained by digestion with pancreatic extract at 50° C. for 1 hr. with sodium metabisulphite as stabiliser of the vitamin during subsequent heat treatment. Mean values obtained by the method were, in µg. per g. fresh liver, ox 1.18, buffalo 1.30, sheep 1.33, goat 1.20, pig 0.59, rabbit 0.60, chicken 0.27, rat 0.052 and mouse 0.75. Values for alkali-stable vitamin B₁₂ activity were obtained for some samples. The

results are discussed with reference to other values reported in the literature.—A. M. Copping.

483

ROBINSON, F. A., FITZGERALD, M. E. H., FEHR, K. and GRIMSHAW, J. J. Vitamin B₁₂ in crude liver extracts. *Nature*, 1954, 174, 558-559. [Res. Div., Allen and Hanburys, Ltd., Ware, Herts.]

Part of the vitamin B₁₂ in crude liver extracts could not be measured with a certain mutant of *Bacterium coli*, and cyanocobalamin added to such extracts was not available for it. The non-available vitamin B₁₂ was not liberated by boiling for a short time but was released in about 4 hr. The released vitamin was apparently recombined if the boiled extract was allowed to stand. The nature of the complex and of the binding substance in liver is discussed with reference to the observations of Wijmenga *et al.* (Absts. 406, Vol. 21; 3089, Vol. 24) and Cooley *et al.* (Abst. 1838, Vol. 21).

BACHER, F. A., BOLEY, A. E. and SHONK, C. E. Radioactive tracer assay for vitamin B₁₂ and other cobalamins in complex mixtures. *Anal. Chem.*, 1954, 26, 1146-1149. [Merck and Co., Inc., Rahway, N.J.]

Vitamin B₁₂ in fermentation broths, feeding mixtures, liquid concentrates, solid concentrates and mixed vitamin capsules was estimated spectrophotometrically after concentration and purification of the vitamin with selective solvents and adsorbing and precipitating reagents. Mixtures of cresol, butanol and Zephiran were used with various resins. In order to confirm the validity

of the method vitamin B₁₂ containing radio-active ⁶⁰Co was added and its recovery at every stage was measured. Samples containing as little as 0.1 µg. vitamin B₁₂ per ml. could be handled successfully. In a series of difficult materials the standard deviation of the results was ± 4.3 per cent.

DOCTOR, V. M. and COUCH, J. R. An unusual example of symbiosis in bacteria. *Arch. Biochem. Biophys.*, 1954, 51, 530-531. [Dept.

N.A. and R., January 1955

Biochem. Nutrit., Texas Agric. Exp. Stat., Agric. and Mech. Coll. System, College Station.]

A relationship of reciprocal advantage was demonstrated between *Lactobacillus leichmannii*, which requires both vitamin B₁₂ and folic acid and produces citrovorum factor in a purified medium, and *Leuconostoc citrovorum*, which requires citrovorum factor and produces vitamin B₁₂ activity.—A. M. Copping.

491

BRADLEY, J. E., SMITH, E. L., BAKER, S. J. and MOLLIN, D. L. The use of the radioactive isotope of cobalt Co⁵⁸ for the preparation of labelled vitamin B₁₂. *Lancet*, 1954, 267, 476-477. [Postgrad. Med. Sch., London.]

The radio-active isotope ⁵⁸Co was incorporated into vitamin B₁₂ by a method previously described for ⁶⁰Co (Abst. 1666, Vol. 23) and found to be as useful as ⁶⁰Co for measuring excretion of vitamin B₁₂. The advantage of ⁵⁸Co in human and biological studies is that it has a half-life of 72 days, whereas that of ⁶⁰Co is 5 years; it is thus possible to use ⁵⁸Co safely in larger amounts. The use of ⁵⁸Co is limited at present by scarcity; when supplies become available, it is considered that it should replace ⁶⁰Co in clinical investigations.

494

FRÖLICH, A. Relation between vitamin D and vitamin B₁₂. *Nature*, 1954, 174, 462-463. [Nat. Animal Exp. Stat., Upsala 7.]

Chicks from a breeding flock not specially depleted of vitamin B₁₂ were fed from one day old to 4 weeks of age on an all-vegetable diet of soya bean oilmeal 16.6, sunflower seed meal 10.5, alfalfa meal 4.0, wheat bran 11.0, minerals 4.6, a vitamin concentrate rich in vitamin B₁, riboflavin, nicotinic acid 1.0, and mixed cereals to 100. At 1 week of age they were divided into 6 groups each with 4 sub-groups of 9 chicks. Each of the 6 main groups was given 200, 640 or 1400 I.U. vitamin D₃ as Deltafor per kg. diet, each level of dosing being given with and without a supplement of 30 µg. vitamin B₁₂ per kg. diet.

With increasing amounts of vitamin D, and with vitamin B₁₂ also, the mean weight gains in 3 weeks were 134, 141 and 144 g., respectively. The corresponding gains without vitamin B₁₂ were 128, 110 and 106 g.—K. J. Carpenter.

BALIGA, B. R., BALAKRISHNAN, S. and RAJAGOPALAN, R. Biological value of proteins as influenced by dietary vitamin B₁₂. *Nature*, 1954, 174, 35-36. [Dept. Biochem., Indian Inst. Sci., Bangalore.]

Previous studies (*Current Sci.*, 1954, 23, 51) showed that vitamin B₁₂ improved the biological value of unheated soya bean protein. It is here reported that the biological value of the protein in soya bean meal tested on rats by the method of Mitchell (*J. Biol. Chem.*, 1924, 58, 873) was enhanced by vitamin B₁₂ or aureomycin irrespective of previous heat treatment. Tests made with rats given casein as protein with heated or unheated inhibitor substance from soya bean showed that although vitamin B₁₂ could overcome the inhibitory effect of the unheated soya preparation it could not raise the biological value of the casein above its normal level. The possibility that greater amounts of vitamin B₁₂ might increase the biological value of casein is under investigation.

YOUNG, R. J., NORRIS, L. C. and HEUSER, G. F. The utilization by vitamin B₁₂-deficient chicks of monomethylaminoethanol, homocystine and betaine as precursors of choline and methionine. *J. Nutrition*, 1954, 53, 233-248. [Agric. Exp. Stat., Cornell Univ., Ithaca, N.Y.]

Chicks from hens receiving a maize and soya bean meal diet were given diets based on soya bean protein and adequate in all amino-acids except methionine and cystine. A supplement of choline alone improved growth and survival, and choline with vitamin B₁₂ was still better. Monomethylaminoethanol combined with betaine permitted good growth and survival with or without vitamin B₁₂; it was slightly more effective in replacing choline when the total methionine and cystine in the basal diet amounted to 0.75 instead of 0.55 per cent. Vitamin B₁₂ did not seem to be essential to the process of transmethylation. A combination of homocystine and betaine also replaced methionine for chicks. If inadequate amounts of betaine were included in the mixture the presence of vitamin B₁₂ was essential, which was evidence that the vitamin was concerned in the synthesis of methyl groups by the chick.

DESSI, P., BARBIERI, L. L., BRUNELLI, M. A. and GIANNI, A. M. Intorno all'azione della vitamina B₁₂ nella steatosi epatica dietetica del ratto albino. [Effect of vitamin B₁₂ on fatty liver induced by diet in the white rat.] *Arch. Sci. biol., Bologna*, 1954, 38, 286-293. [Ist. Chim. Biol., Univ. Bologna.]

When groups of 6 adult rats received the diet of Handler (Abst. 749, Vol. 18) with or without vitamin B₁₂ given orally or subcutaneously, there was no difference in the liver content of total lipids. The experiment lasted for from 22 to 45 days.

When the experiment was repeated with less protein and more fat in the diet, and an amount of L-cystine to supply 10 mg. per kg. bodyweight daily, subcutaneous injection of 100 µg. vitamin B₁₂ per kg. bodyweight daily greatly reduced the amount of total fat, and increased the amount of glycogen, in the liver.

When young rats for 63 days from weaning were given the diet of Handler without added L-cystine,

addition of vitamin B₁₂ reduced liver total fat and choline, considerably at first, but the effect disappeared gradually as the age of the animals increased. There was a beneficial effect also on growth.

Histological examination of the livers was made.

AMSOHLER, J. W. and PAMMER, H. Brat- und Backhühnermastversuch mit Terramycin und Vitamin B₁₂ (Bi-Con TM3 + 3) bei verschiedenen Stufen tierischen Eiweisses. [Fattening of roasting fowls with terramycin and vitamin B₁₂ at different intakes of animal protein.] *Arch. Geflügelk.*, 1954, 18, 197-202. [Inst. Tierzucht, Hochsch. Bodenkultur, Vienna.] English summary.

Diets in which 49.3, 36.4 or 26.3 per cent. of the protein was from animal sources were given to year-old chicks with addition of vitamin B₁₂ and terramycin concentrate. A fourth group received the highest amount of animal protein but no concentrate. In all, 248 birds were fattened for 8 weeks; in comparison with the group without supplement, the addition of the concentrate improved the weight gain and feed utilisation by 16.4, 15.1 and 12.6 per cent., respectively. It thus appeared that with vitamin B₁₂ and terramycin added half the protein in the ration could be replaced by plant protein to give better growth and utilisation of feed.—A. M. Copping.

CARLSON, C. W., GUENTHNER, E., KOHLMAYER, W. and OLSON, O. E. Some effects of selenium, arsenicals, and vitamin B₁₂ on chick growth. *Poultry Sci.*, 1954, 33, 768-774. [S. Dakota Agric. Exp. Stat., College Station.]

Crossbred and New Hampshire chicks were given a practical diet or the same diet modified by replacing part of its maize by seleniferous maize so that the ration contained 10 p.p.m. Se. The addition to either of the diets of sodium arsenite, arsenic acid or 3-nitro-4-hydroxyphenylarsonic acid significantly improved the growth of the crossbred chicks, the improvement being, in general, greater with the practical diet. The growth of the New Hampshire chicks was only slightly influenced by any of the compounds. In another experiment, in which the diet contained maize and soya bean meal, with or without the addition of 10 p.p.m. Se as sodium selenite, toxic signs, as reflected in impaired growth, were observed only when a vitamin B₁₂ supplement was given. The toxicity was only partly counteracted by sodium arsenite or arsenic acid. The results suggested that different breeds differ in their tolerance to Se poisoning and in their response to arsenical drugs.

MAGRUDER, N. D., BLETNER, J. K., CLARK, T. B. and WEAKLEY, C. E. (Jr.) The variable response of normal chicks to stress rations and a vitamin B₁₂ supplement. *Poultry Sci.*, 1954, **33**, 511-518. [W. Virginia Agric. Exp. Stat., Morgantown.]

Chicks from New Hampshire hens receiving rations containing vitamin B₁₂ were given diets containing 35 or 70 per cent. soya bean meal with or without the addition of iodinated casein. Growth was retarded, with decreasing degrees of severity, when the ration contained: 70 per cent. soya bean meal with 0.1 per cent. iodinated casein; 70 per cent. soya bean meal; 35 per cent. soya bean meal with 0.1 per cent. iodinated casein. When the rations were supplemented with vitamin B₁₂, growth and efficiency of feed utilisation were much increased. The response of the chicks to the abnormal rations and to supplements of vitamin B₁₂ varied between hatches, and the difference was ascribed to variation in the amount of vitamin B₁₂ transmitted to the chick through the egg. Faulty feather structure was seen in chicks given the ration containing 70 per cent. soya bean meal, and was not prevented by supplements of folic acid or vitamin B₁₂ or both. In chicks receiving iodinated casein for 4 weeks, an excessive amount of black colour appeared in the feathers.

BENTLEY, O. G. and HERSHBERGER, T. V. The effect of antibiotics on hatchability of hens' eggs and progeny growth performance. *Poultry Sci.*, 1954, **33**, 641-648. [Dept. Animal Sci., Ohio Agric. Exp. Stat., Wooster.]

Experiments, lasting for from 16 to 20 weeks, were made on one-year-old pullets receiving an all-vegetable ration and maintained in pens on wood shavings which were changed monthly. The hatch from the eggs was not consistently improved by giving bacitracin, terramycin, aureomycin HCl or procaine penicillin. Bacitracin added to a breeding diet lacking vitamin B₁₂ significantly improved the growth of the progeny if the rearing diet also lacked vitamin B₁₂. Aureomycin had a similar but less pronounced effect. If the hens' diet contained vitamin B₁₂ the further addition of antibiotics had no significant effect on the growth of the chicks. The addition of bacitracin or aureomycin did not affect the vitamin B₁₂ content of the egg yolks or of the livers of the chicks or hens. It is suggested that a growth factor other than vitamin B₁₂ may be transmitted to the egg when bacitracin or aureomycin is given.

RUSOFF, L. L. and HAQ, M. O. Studies on aureomycin and vitamin B₁₂ supplementations for

Vol. 25, No. 1

dairy cows. 2. Effect on production, composition, and vitamin B₁₂ content of the milk. *J. Dairy Sci.*, 1954, **37**, 677-683. [Dairy Dept., Louisiana State Univ., Baton Rouge.]

Three groups of 5 lactating Holstein cows were given a protein and grain ration with or without an aureomycin supplement supplying 130 mg. per head daily, or a vitamin B₁₂ supplement giving 0.83 mg. daily. Neither supplement had any effect on milk production or on the fat, total solids, solids-not-fat, total protein, casein, ash, Ca or P of the milk. Addition of vitamin B₁₂ did not increase the amount of the vitamin in the milk. A further trial was made on 4 groups of 5 cows having no vitamin B₁₂ supplement or 1.66, 2.49 or 3.32 mg. per head daily in the grain ration. No difference in milk production or in the vitamin B₁₂ content of the milk was recorded, but there was a significant decrease in the fat content of the milk of the cows given vitamin B₁₂. With only 0.83 mg. vitamin B₁₂ per head daily in the ration there was no decrease in the fat content.—A. M. Copping.

505

FERRANDO, R., PHILIPPE, J. and PETIT, A. La vitamine B₁₂ dans la ration du porc. [Vitamin B₁₂ in the ration of pigs.] *Rev. Méd. vét., Toulouse*, 1954, **105**, 355-360.

In tests with young pigs lasting 105 days, no significant difference in weight gain or food consumption was recorded between groups given a mixed diet with or without a supplement of 20 µg. vitamin B₁₂ per kg. diet. In a further study lasting 60 days some animals received only vegetable protein and others had mixed animal and vegetable protein. Again supplements of vitamin B₁₂ had no demonstrable effect on growth. The results are discussed with reference to the literature, and it is suggested that attention to the balance of the ration is more important than the addition of special supplements. A plea is made for wise use of new knowledge in animal nutrition.

506

MUSTAKALLIO, K. K. and TELKKÄ, A. Effect of aureomycin, vitamin B₁₂, folic acid and aminopterin on the metamorphosis of tadpoles. *Ann. Med. exp. Biol. Fenn.*, 1954, **32**, 9-14. [Dept. Anat., Univ. Helsinki.]

Eight groups of 50 tadpoles, from 13 to 15 mm. long, without discernible hind legs, were kept in tap water with ground beef as food and added aureomycin, vitamin B₁₂, folic acid, or aminopterin alone or with aureomycin, vitamin B₁₂ or folic acid. At the stage when the forelegs developed the tadpoles were killed and weighed. Metamorphosis to this stage was delayed in those given aureomycin or aminopterin, and the two together caused severe retardation. Vitamin B₁₂ or folic

acid was without effect on metamorphosis. Vitamin B₁₂ showed some protective action against the growth-retarding effect of aminopterin, but folic acid did not.—A. M. Copping.

507

KANO, A. K., ANDERSON, J. A., HUGHAM, D. F. and CHARKEY, L. W. A possible role of iodinated casein in intestinal assimilation of vitamin B₁₂. *Proc. Soc. Exp. Biol. Med.*, 1954, 86, 8-11. [Dept. Chem., Colorado Agric. and Mech. Coll., Fort Collins.]

Groups of 50 day-old chicks were given a diet of maize and soya bean meal with or without addition of iodinated casein for a preliminary period of 15 days, after which some of each group were killed. The remaining birds in each group were then divided into two groups, one continued as before and the other given 25 µg. crystalline vitamin B₁₂ per kg. diet. At 4 weeks of age all the birds were killed and vitamin B₁₂ in the liver and caecal contents was measured. Iodinated casein in the diet reduced the vitamin B₁₂ content of the liver unless the vitamin was given in the diet. When the vitamin was added to the diet containing iodinated casein, vitamin B₁₂ increased in the caecal contents. The findings suggested that iodinated casein interfered in some way with the absorption of vitamin B₁₂ from the intestine, which might partly explain the increased sensitivity to vitamin B₁₂ depletion of chicks given iodinated casein.—A. M. Copping.

508

VENKATARAMAN, P. R. and FRIEDEL, M. T. The effects of induced hyperthyroidism and vitamin B₁₂ on the synthesis of some phosphate fractions in the rat liver. *Endocrinology*, 1954, 54, 612-619. [Hektoen Inst. Med. Res., Cook County Hosp., Chicago, Ill.]

Weanling rats were given a purified diet with 2 µg. vitamin B₁₂ a week, or with 0.2 per cent. iodinated casein alone or supplemented for 2 weeks with vitamin B₁₂. After 4 weeks on the diets the animals were fasted for from 10 to 12 hr. and were then injected with about 10 µg. radio-active disodium phosphate per 100 g. bodyweight. Six hr. later the rats were killed by bleeding under Nembutal anaesthesia, and the livers were removed for analysis. Total acid-soluble, phospholipin, pentose nucleic acid, deoxypentose nucleic acid, and phosphoprotein phosphorus fractions were estimated and their radio-activity was measured. Hyperthyroidism induced by iodinated casein reduced the uptake of ³²P in the total acid-soluble fraction and the effect was counteracted by administration of vitamin B₁₂; there was an increase in the phospholipin content of the liver tissue which was not affected by vitamin B₁₂.

Pentose nucleic acid synthesis was increased and reduced again when vitamin B₁₂ was given. No effect of hyperthyroidism or of vitamin B₁₂ was seen on the deoxypentose nucleic acid and phosphoprotein fractions.—A. M. Copping.

509

GUGGENHEIM, K. and HALEVY, S. The effects of vitamin B₁₂, organ extracts, yeast and antibiotics on emetine toxicity in rats. *J. Nutrition*, 1954, 53, 129-138. [Lab. Nutrit., Dept. Biochem., Hadassah Med. Sch., Hebrew Univ., Jerusalem.]

Rats of from 40 to 50 g. weight were given purified diets containing 3, 9, 15 or 18 per cent. casein for 3 weeks before daily injection was begun of 0.3 mg. emetine per 100 g. bodyweight. The survival time before death from emetine poisoning was used as the index of drug tolerance, and the effect on it was studied of giving extracts of dried liver powder, fresh beef muscle, heart, or kidney, or aureomycin, streptomycin, amino-acids, yeast, or vitamin B₁₂. Resistance to emetine was less on a low-protein diet and was significantly improved by all the supplements except yeast. In rats given adequate protein, extracts of liver, muscle, heart and kidney increased resistance to emetine but antibiotics and vitamin B₁₂ were without effect.

In another experiment without emetine, the N content of the liver was estimated in protein-depleted rats, of which some were given amino-acids, liver extract, hydrolysed liver extract, vitamin B₁₂ or aureomycin. The amino-acids and hydrolysed liver extract increased the N content of the liver, but the unhydrolysed liver extract had no such effect, and it is concluded that the protective effect of liver extract against emetine was not due to its amino-acid content.—A. M. Copping.

ROSENTHAL, H. L. and BROWN, C. L. (Jr.) (with ATEs, W. and GEER, B.) Vitamin B₁₂ activity of plasma and whole blood from various animals. *Proc. Soc. Exp. Biol. Med.*, 1954, 86, 117-120. [Dept. Med., Tulane Univ. Sch. Med., New Orleans, La.]

Vitamin B₁₂ activity was measured with *Lactobacillus leichmannii* in the whole blood and plasma before and after treatment with alkali and in some samples after hydrolysis. Wide variations were found in the values, in µg. per ml., ranging from 0.38 for human blood to 43.3 for rabbit blood, and from 0.16 for human plasma to 31.3 for rabbit plasma. Dog, calf, chicken and alligator blood gave values of 0.33, 0.31, 8.57 and 7.14, respectively. In mammals vitamin B₁₂ appeared to be almost equally divided between the blood cells and plasma. In the chicken and alligator most of the activity was in the nucleated erythrocytes.—A. M. Copping.

511

KARLIN, R. La vitamine B₁₂ dans le lait humain et bovin. [Vitamin B₁₂ in human and cow's milk.] *C.R. Soc. Biol.*, 1954, 148, 371-373.

Vitamin B₁₂ was satisfactorily extracted from human milk, which offers certain difficulties, by treatment with a solution of CaCl₂ in presence of KCN, and was estimated with *Lactobacillus leichmannii* in human and cow's milk. In 12 samples of human milk in Lyons obtained during the first week of lactation, the values ranged from 0.25 to 2.36, mean 0.92, μg . per ml. From the first to the eighth month the mean values ranged from 0 to 0.66, with a tendency to decrease as lactation progressed. In 16 samples of mixed cow's milk in Lyons the mean value was 3.9.—A. M. Copping.

512

VIALARD-GOUDOU, A., LAMBIN, S., GERMAN, A. and BRIEAT, J. Étude de l'activité vitaminique B₁₂ de la sauce de poisson vietnamienne "nuoc-nam". [Vitamin B₁₂ content of the Viet-Nam fish sauce nuoc-mam.] *C. R. Acad. Sci.*, 1954, 238, 2193-2195.

A microbiological method with a mutant of *Bacterium coli* was used to measure the vitamin B₁₂ potency of nuoc-mam, which is prepared from fish decomposed by anaerobic bacteria. Values ranging from 25 to 200 μg . per litre were found for preparations from different areas. The highest value was for a sauce made from freshwater fish. All others were from marine fish. (See Abst. 2781, Vol. 23).—A. M. Copping.

OTHER B VITAMINS

513

FRAENKEL, G. The distribution of vitamin B₇ (carnitine) throughout the animal kingdom. *Arch. Biochem. Biophys.*, 1954, 50, 486-495. [Dept. Entomol., Univ. Illinois, Urbana.]

Vitamin B₇ activity was estimated with larvae of *Tenebrio molitor* by methods previously described (Absts. 554, Vol. 22; 3114, Vol. 24) in single organs or in the whole body of marine invertebrates and in some organs of marine vertebrates. An amount of 0.35 μg . carnitine per g. dry weight of material was taken as the smallest required for maximum survival and good growth; in some cases longevity did not correspond with maximum growth.

Carnitine was found in all preparations, but there were great differences of concentration. Low values were generally attributable to the nature of the original material, which sometimes contained large amounts of inorganic salts.

A very high value, 35 mg. per g. dry weight, was found in the muscle of horseshoe crab, *Limulus polyphemus*. High values were found also in the hepatopancreas and intestine of the same crab, in the worm, *Arenicola*, the adductor muscles, both smooth and striated, of the bivalve, *Venus*, the hepatopancreas and foot of the snail, *Busycan*, the muscle of the crab, *Libinia*, and the hepatopancreas of the crab, *Pagurus*. The electric organ of *Torpedo*, which is a modified gelatinous muscle of high water content, contained from 2240 to 5600 μg . per g. dry matter.

The carnitine content of muscle was studied in relation to the muscle's activity. Carnitine content was relatively high in the flight muscles of the housefly, *Musca domestica*, but the sarcosomes, the principal site of enzyme activity in intermediary

Vol. 25, No. 1

carbohydrate metabolism, had none. In the livers and skeletal muscles of chicks receiving normal or sterilised diets the amounts were the same, as well as in normal rabbits and in one suffering from muscular dystrophy due to vitamin E deficiency; a calf with muscular dystrophy had normal values. The breast muscle of the bat, *Myotis lucifugus*, had values slightly below the average for mammals though its liver values were extremely high. It thus appeared that there was no correlation between carnitine content and activity of muscle.—V. R. Jackson.

514

MORUZZI, G., RABBI, A., VIVIANI, R. and MARCHETTI, M. Ricerche sul contenuto in acido orotico della caseina priva di F.P.A. [Studies on the orotic acid content of casein free from animal-protein factor.] *Acta vitaminol.*, 1954, 8, 135-136. [Ist. Chim. Biol., Univ. Bologna.] French, English, German and Spanish summaries.

Casein, purified as previously described (Absts. 425, 3530, Vol. 21) and unpurified, was extracted with water. The extract was filtered and concentrated. The content of orotic acid in the extracts, estimated with *Lactobacillus bulgaricus* by the method of Wright *et al.* (Abst. 797, Vol. 21), for 4 samples, was equivalent in μg . per g. casein to from 25.43 to 26.76 in crude casein, and to from 3.85 to 4.74 in purified casein.—E. M. Hume.

515

SMITH, L. H. (Jr.) and STETTEN, D. (Jr.) Biosynthesis of orotic acid from citrulline. *J. Amer. Chem. Soc.*, 1954, 76, 3864-3865. [Div.

Nutrit. Physiol., Pub. Health Res. Inst., City of New York, Inc.]

Slices from pigeon or rat liver were incubated in a medium containing bicarbonate, glucose, adenosine triphosphate, carrier orotic acid and either L-citrulline labelled with ^{14}C in the ureide C atom together with L-aspartate, or L-arginine HCl labelled in the amidine C atom together with fumarate. Orotic acid was recovered from the medium and converted to BaCO_3 , in which the radio-activity was measured by Geiger Müller counter.

A significant amount of radio-active orotic acid from citrulline was found in the rat but not in the pigeon liver preparation. The probable pathway is suggested as citrulline + aspartate \rightarrow (argino-succinate) \rightarrow ureidosuccinate \rightarrow (dihydro-orotate) \rightarrow orotic acid. Radio-active orotic acid was not obtained from arginine in either rat or pigeon liver slices.—A. Hepburn.

516

HURLBERT, R. B. and REICHARD, P. Conversion of orotic acid to uridine phosphates by soluble enzymes of liver. *Acta chem. scand.*, 1954, 8, 701-702. [Dept. Biochem., Karolinska Inst., Stockholm.]

Soluble enzymes were prepared from rat or pigeon liver by the method of Saffran and Scarano (*Nature*, 1953, 172, 949) and conversion of orotic acid-2- ^{14}C was obtained with fructose-1 : 6-diphosphate or ribose-5-phosphate in presence of diphosphopyridine nucleotide, adenosine triphosphate and Mg ions. Products were separated chromatographically and 5 radio-active fractions were obtained, uridine-5-phosphate, 3 others shown by acid hydrolysis to contain uridine-5-phosphate and a fifth, in the effluent from the column. Uridine-5-phosphate was the first detectable product of the reaction and uridine appeared not to be an intermediate in the incorporation of orotic acid into the uridine-5-phosphate derivatives. The preparations from the rat and pigeon differed in their effectiveness for promoting the incorporation.

517

TRIA, E. and BARNABEI, O. Ricerche su un fattore di accrescimento dei lieviti e dei ratti presente nel fegato. [Studies on a growth factor for yeasts and for rats, present in the liver.] *Arch. Sci. biol., Bologna*, 1954, 38, 383-416. [Ist. Fisiol. Gen., Univ. Ferrara.]

A considerable review of the subject is given. The amount was measured by CO_2 evolved by cultures of brewer's yeast, in a medium of glucose and salts, on addition of liver preparations. A protein-free filtrate of fresh ox liver pulp had the same stimulatory activity as the filtrate before removal of protein. Autolysis of the liver pulp did not affect the activity of the extract, and subsequent boiling for an hour reduced it only slightly. Removal of amino-acids and polypeptides had no effect on the activity. When the culture medium contained, as well, asparagine, vitamin B₁, nicotinamide, vitamin B₆, Ca pantothenate, inositol and biotin, the response to addition of liver extract was even greater, and the foregoing results were confirmed. Activity of the liver extract was maintained after it had been autoclaved at 125°C. for an hour. Growth was measured turbidimetrically, and the results agreed with those obtained by measuring evolution of CO_2 . The substance was soluble in ethanol and acetone, and insoluble in ether, butanol and amyl alcohol. It was dialysable and stable to acid and, unlike vitamin B₁₂, to alkali. It did not give the biuret or ninhydrin reaction. It had an absorption maximum at 262 m μ . The activity of the substance in any preparation was not proportional to the preparation's anti-anæmic activity.

Twenty synthetic thiazole compounds and certain formyl compounds were tested for their power to stimulate fermentation in the conditions described. Some of them had some activity.

Experiments with rats showed that the substance was able to counteract the unfavourable effect of desiccated thyroid on growth, and that growth was stimulated by giving the substance to rats already receiving vitamin B₁₂.

It is stressed that the factor is stimulatory but probably not indispensable.—E. M. Hume.

VITAMIN C (ASCORBIC ACID)

518

FABIANEK, J. Recherches sur les "vitamines P", le scorbut expérimental et la fragilité vasculaire. 4. Essais de régimes alimentaires artificiels en vue de l'établissement d'une formule convenant au cobaye. 5. Régimes artificiels assurant au cobaye une bonne croissance et une longue survie. [Research on "vitamin P", experimental scurvy and vascular fragility.

4. Tests with artificial diets to find a formula suitable for the guineapig. 5. Artificial diets producing good growth and survival in the guineapig.] *Bull. Soc. Chim. biol.*, 1954, 36, 851-858; 859-868. [Lab. Chim. Agric., Conservatoire Nat. Arts et Métiers, Paris.]

For previous parts see Absts. 3575, Vol. 21; 607, 2172, Vol. 22.

4. Two artificial diets were made up and tested

N.A. and R., January 1955

on guineapigs. They were modifications of one previously described. Only 40 per cent. of animals survived more than 35 days. Those which accepted the diets grew well for from 3 to 4 months and then began to lose weight, at first slowly and then rapidly, until they died. With the rapid loss of weight, general debility and indefinite intestinal disturbances were seen but no sign of scurvy or of vascular fragility. The fault in the diet was not repaired by making it alkaline, or by adding certain B vitamins or galacturonic acid.

5. A diet suggested by Elvehjem and his colleagues (Abst. 5180, Vol. 19) was then tested and found satisfactory. One of the diets mentioned in Part 4 was modified to contain soya bean oil and cellulose with a vitamin B complex supplement similar to that of Elvehjem's diet. On the modified diet good growth was obtained with survival beyond 300 days. The guineapigs on the artificial diet were given 20 mg. ascorbic acid daily and showed no sign of scurvy.

A. M. Copping.

GORI, E. Modifiche al metodo di Roe-Kuether per il dosaggio dell'acido ascorbico tessutale. [Modification of Roe and Kuether's method for estimating tissue ascorbic acid.] *Arch. Sci. biol., Bologna*, 1954, 38, 221-233. [Inst. Pharmacol., Univ. Milan.]

It was sought to adapt the method of Roe and Kuether (Abst. 261, Vol. 13), as originally described, to the rapid estimation of ascorbic acid in the adrenal cortex and other organs. Incubation for 30 min. at 80° C. gave the same result as for 3 hr. at 37° C. It was found possible for convenience to store the fresh tissue for 24 hr. at 2° C. or to suspend for several hours or a whole night the process of extracting the tissue with trichloroacetic acid. Preparation of a satisfactory sample of activated carbon is described, and the possibility was examined of substituting for that stage of the method, the oxidation with Br water recommended by Meyer *et al.* (Abst. 1709, Vol. 23); the results obtained were, however, always much too high.—E. M. Hume.

PROCHÁZKA, Ž. and ŠANDA, V. 7. Výskt askorbigenu v některých druzích seleniny. [7. Ascorbigen content of certain vegetables.] *Chem. listy*, 1953, 47, 1643-1646; 1954, 48, 898-901. [Inst. Org. Chem. ČAV, Prague.]

Two substances containing ascorbic acid were isolated chromatographically from crude ascorbigen. They contained nitrogen, probably in the form of an indol derivative.

A. Jančářík (Czechoslovakia).

524

PROCHÁZKA, Ž. Ascorbigen. [Ascorbigen.] *Šborn. pathofys. tráv.*, 1954, 8, 13-20. [Inst. Org. Chem. ČAV, Prague.] English and Russian summaries.

A historical summary is given of knowledge about ascorbigen and of some early information about its importance in diet. The known properties of ascorbigen from *Brassica oleracea* are described in detail. Ascorbigen is not a protein; its molecular weight is 400; hydrolysis with HCl produces a violet-coloured derivative. The ultraviolet spectrum of ascorbigen is similar to that of leucoanthocyanins or tannins. On paper chromatograms, it gives a weak reaction for phenols with the Folin Denis reagent. It is highly labile at low

pH, but is resistant to oxidising agents. The molecule of ascorbigen has antiscorbutic activity about $\frac{1}{2}$ or $\frac{1}{3}$ that of ascorbic acid.

M. Prokšová (Czechoslovakia).

YASHIMA, K. Biochemical studies on 2-ketogulonic acid methylester. 5. On the mechanism of the formation of vitamin C from 2-ketogulonic acid methylester. *Kurume Med. J.*, 1954, 1, 1-10. [Dept. Med. Chem., Sch. Med., Univ. Kurume, Kurume-shi, Japan.]

From a series of experiments on the production of vitamin C from 2-ketogulonic acid methyl ester in presence of an extract prepared from fresh cow's muscle, the conclusion is drawn that vitamin C is formed from 2-ketogulonic acid methyl ester directly and not through an intermediary product. The results support the hypothesis that enolisation of the substance takes place, and that the cis-forms of the enol compounds form a lactone which yields ascorbic acid.—M. B. Richards.

GANGULI, N. C., ROY, S. C. and GUHA, B. C. Biosynthesis of L-ascorbic acid. *Nature*, 1954, 174, 511-512. [Univ. Coll. Sci. Technol., Calcutta 9.]

Previous work by Roy *et al.* (Abst. 2885, Vol. 16) and Ghosh (*J. Indian Chem. Soc.*, 1946, 23, 99) suggested that pyruvic acid is a precursor of ascorbic acid in the rat. The incubation of liver tissue with sodium pyruvate under suitable conditions has also been shown to produce an increase of from 15 to 20 per cent. ascorbic acid. In the presence of vitamin B₁ the increase was more than 30 per cent.

Radio-active ascorbic acid and the 2:4-dinitrophenylhydrazine derivative of dehydroascorbic acid were isolated by column chromatography from the urine of rats treated with chlorotone and radio-active pyruvamide (CH₃¹⁴COCOONH₂). With the use of paper chromatography and radioautography, glucose-1-phosphate, glucose-6-phosphate, fructose-1:6-phosphate, dl-glyceraldehyde phosphate, dihydroxyacetone phosphate, 3-phosphoglyceric acid, phosphopyruvic acid, citric,

α-ketoglutaric, succinic, fumaric and malic acids, and 15 amino-acids were isolated from the liver, and the absence from them of ¹⁴C was demonstrated, but liver glycogen was found active.

KUSANOV, V. A., KRAIKO, E. A., PENAR, O. I., TRUFANOV, A. V. and YANOVSKAYA, B. I. Biosintez vitamína C u tsipyat v zavisimosti ot nalichiya v ratsione folievoi kisloty ili ee proizvodnykh. [Biosynthesis of vitamin C in the chicken in relation to the amount of folic acid or its derivatives in the diet.] *Biokhimiya*, 1953, 18, 351-353. [Inst. Pitan., Akad. Med. Nauk SSSR.]

Deprivation of pteroylglutamic acid in chickens was followed by an increase in the ascorbic acid content of the spleen, from 35.6 to 50.7 mg. per cent., the cause of which is considered to be a compensating increase in the functional activity of the spleen. When pteroylaminoipimelic acid was given to chicks suffering from pteroylglutamic deficiency, the high level of ascorbic acid in the spleen was maintained, 55.3, 46.7 and 46.4 mg. in 3 tests. Pteroylaminoazelaic acid behaved like pteroylglutamic acid, the ascorbic acid content of the spleen being 37.8 mg. per cent. The conclusion that the aminoazelaic compound had vitamin activity was confirmed by observations on the development of feathers in the chickens.—W. Hughes.

PROZOROVSKAYA, L. L. Soderzhanie magniya v zubakh i kostyakh morskikh svinovok pri eksperimental'noi tzyznye i posle ee lecheniya. [Content of magnesium in teeth and bones in guinea pigs in experimental scurvy and after its cure.] *Stomatologiya*, 1954, No. 1, 20-24. [Dept. Biol. Chem., Med. Stomatol. Inst., Leningrad.]

In experimental scurvy the Mg content of guinea pigs' teeth was considerably less than normal. It continued to fall for 2 weeks while vitamins C and P were being given, and when signs of scurvy were disappearing; after 2 months of supplementary feeding, however, the Mg content of the molars was normal and that of the incisors nearly so. The Mg content of the bones was little affected by the disease.—H. Scherbatoff.

531

BONOMO, E. and CHIRICO, M. Sul comportamento dei glicoproteidi serici nello scorbutto sperimentale della cavia. [The behaviour of the

serum glycoproteins in experimental scurvy of the guinea pig.] *Acta vitaminol.*, 1954, 8, 173-176. [Inst. Clin. Med., Univ. Milan.] French, English, German and Spanish summaries.

Of 20 guineapigs fed on a scorbutogenic diet, 10 received 75 mg. ascorbic acid daily by mouth. After 20 days they were killed, and analyses were made on the blood serum. In the scorbutic animals there was a great increase in the perchloride-soluble mucoproteins, the total protein polysaccharides, and the glucosamines bound to the total serum protein.—E. M. Hume.

532

ALLEGRETTI, N. and VUKADINOVIĆ, G. (with URAIC, G.) Effect of ascorbic acid on insulin sensitivity in the rat. *Amer. J. Physiol.*, 1954, 177, 264-268. [Inst. Physiol., Med. Fac., Univ. Zagreb, Yugoslavia.]

The medulla of the adrenal glands was destroyed by paravertebral incision in albino rats weighing from 110 to 135 g., and 3 weeks were allowed for regeneration of the adrenal cortex. Together with normal rats they then received an intraperitoneal injection of 0.1 g. ascorbic acid every hour for 4 hr. The fasting blood sugar value of the treated rats was below that of the normal rats, and the injections of ascorbic acid had no significant effect.

Ascorbic acid or saline was given as just described to rats previously injected subcutaneously with 0.1125 units of insulin. Half the animals had the adrenal medulla destroyed and half were intact. Removal of the medulla increased the sensitivity to insulin. Administration of ascorbic acid heightened the action of insulin in intact rats and rats with the medulla destroyed. The same experiment was made with a dose of 0.0625 units of insulin but it proved too small to show a difference between animals given and not given ascorbic acid.—A. Hepburn.

SANFORD, P. E., WEI, A. J. and CLEGG, R. E. Vitamin C and tyrosine metabolism in the chicken. *Poultry Sci.*, 1954, 33, 585-589. [Kansas Agric. Exp. Stat., Manhattan.]

Groups of chicks were fed on a basal diet supplemented with 2.5, 5.0, 7.5 or 10 per cent. tyrosine, up to the age of 3 or 4 weeks. With more than 5 per cent. tyrosine, growth was slowed; with 7.5 and 10 per cent. there was high mortality and abnormal feathering. Ascorbic acid added to the tyrosine diet eliminated these effects but when it was given separately into the mouth the chicks developed soft beaks and did not eat well. Folic acid, 100 mg. per 100 g. feed, had no effect with a 7.5 per cent. tyrosine diet. When tyrosine metabolites were estimated in the urine of 3 hens fed on a commercial ration with 7 g. tyrosine daily,

homogentisic acid and keto-acid values were low for 12 days, then rose sharply. Administration of ascorbic acid lowered the values to the original level.—A. Hepburn.

534

REDDI, K. K. and NÖRSTROM, A. Influence of vitamin C on the utilization of sulphate labelled with sulphur-35 in the synthesis of chondroitin sulphate of the costal cartilage of the guinea pig. *Nature*, 1954, 173, 1232-1233. [2. Chem. Dept., Caroline Inst., Stockholm.]

Of 2 groups of 26 guineapigs of both sexes, maintained on a scorbutogenic diet, one group received no supplement, and developed scurvy; the other received 4 mg. l-ascorbic acid daily and remained healthy. On the 19th day the animals in both groups were given intraperitoneally 0.02 mC. $\text{Na}_2^{35}\text{SO}_4$ per 100 g. bodyweight in dilute aqueous solution. After 48 hr. they were killed and the costal cartilage was removed; chondroitin sulphate prepared from it was precipitated as BaSO_4 , and the radio-activity was measured by Geiger Müller counter. The amount of radioactive sulphate incorporated into the chondroitin sulphate of the costal cartilage by the normal animals was 3 times that by the deprived. No significant difference was found between the sexes. The technique appeared to offer a sensitive measurement of the disturbance of cartilage metabolism in scurvy.—A. Hepburn.

BACCHUS, H. Ascorbic acid and urinary steroid excretion. *J. Clin. Endocrinol.*, 1954, **14**, 744-746. [Dept. Physiol., Sch. Med., George Washington Univ., Washington, D.C.]

In a letter referring to the report of Klein *et al.* (Abst. 3708, Vol. 24) that the administration of ascorbic acid to human subjects reduced the excretion of "blue chromogen" substances but not of 17-ketosteroids in the urine, the author recalls his own findings (Title 3019, Vol. 23; Abst. 4412, Vol. 23) that the rise in excretion of 17-ketosteroids seen in adrenalectomized female rats given cortisone was prevented by ascorbic acid. Unpublished results (1952) showed that ascorbic acid had no effect on the increase of urinary 17-ketosteroids after injection of dehydroepiandrosterone into similar rats. Intact rats treated with ascorbic acid had only a slight decrease.

The results suggested that ascorbic acid acted not on endogenous or secreted 17-ketosteroids but on their formation from the injected cortisone. Experiments *in vitro* with liver tissue (Abst. 1873, Vol. 24; *Endocrinology*, 1953, **53**, 617) confirmed the conclusion. The probable reason why ascorbic acid fails to produce any great change in the amount of urinary 17-ketosteroids in the intact organism is that the greater part of the urinary 17-ketosteroids is derived from the testes or ovaries and from the secretion of the adrenal cortex. Some is derived from the metabolism of C-21 corticosteroids.

The "blue chromogens", which include dehydroepiandrosterone, are considered to be derivatives of certain C-21 corticosteroids and constitute only from 20 to 30 per cent. of the total 17-ketosteroids in urine. Hence a large decrease affects the total urinary 17-ketosteroids to only a small extent. The results of Klein *et al.* were essentially in agreement with the author's, and were interpreted as indicating that, in the intact subject, ascorbic acid can depress the excretion of certain substances including metabolites of certain adrenocortical hormones.—A. Hepburn.

539

BELAVADY, B. and BANERJEE, S. Metabolism of cholesterol in scorbutic guinea pigs. *J. Biol. Chem.*, 1954, **209**, 641-645. [Dept. Physiol., Presidency Coll., Calcutta.]

Chronic scurvy was produced in male guineapigs by feeding them on the diet described by Banerjee (Abst. 2319, Vol. 15). To prolong their survival time they received daily an oral supplement of 0.25 mg. ascorbic acid. The ability to acetylate

p-aminobenzoic acid was tested over several weeks in them and in animals given 5 mg. ascorbic acid daily. They were then killed and cholesterol was estimated in certain organs.

During the progress of scurvy the capacity to acetylate *p*-aminobenzoic acid diminished; the cholesterol content of the adrenal glands, spleen and lungs fell, that of the testes and small intestine increased significantly; the liver and kidney showed no change. It is suggested that the disturbance of cholesterol metabolism in the guineapig deprived of vitamin C may be responsible for the lowered function of the adrenal gland which was previously demonstrated.—G. A. Garton.

ČERMÁK, O. Vylučování kyseliny askorbové u králků po aplikaci hormonů předního laloku hypofyzy. [Excretion of ascorbic acid by the rabbit after administration of hormones of the anterior pituitary gland.] *Sbor. VŠZ, Brno*, 1953, 155-162. [Inst. Anat., Agric. Univ., Brno.] English and Russian summaries.

The excretion of ascorbic acid given by intramuscular injection, and its relation to the previous administration of an extract of the anterior pituitary gland (Antephysol) was studied in non-pregnant doe rabbits.

The excretion of doses of from 40 to 60 mg. in 6 of 8 animals occurred in 2 phases, from 17 to 30 hr., and from 94 to 122 hr., after the administration. When 100 mg. Antephysol was injected before the administration of 60 mg. ascorbic acid, the first phase did not take place at all in 7 of 11 animals, and the second was delayed in 7 of 11 animals by 30 hr. on the average. The total amount of ascorbic acid excreted in most of the does was less than in control rabbits.

A. Jančařík (Czechoslovakia).

SKOLOFF, B., EDDY, W. H., POWELL, R., BEAUMONT, J. and RELOS, H. Ascorbic acid analog in experimental leukemia. *Cancer*

N.A. and R., January 1955

Res., 1954, 14, 307-310. [Southern Bio-Res. Lab., Florida Southern Coll., Lakeland.]

Of 45 normal mice aged about 5 months, 15 were maintained on Purina chow, 15 on a scorbutogenic diet with 0.75 per cent. of the ascorbic acid analogue, D-glucoscorbic acid, and 15 on the same diet with 1 per cent. analogue. Forty-five mice of a strain with a high incidence of lymphocytic leukaemia, and already at 8 months showing signs of it, were treated in the same way. Ascorbic acid was estimated in the blood plasma; the value after 15 days had fallen from 1.05 mg. per 100 ml. almost to nil in all 4 groups having the experimental diets.

In a similar experiment, the ascorbic acid content of the spleen and adrenal glands fell to a very low value after 13 days of the diet with 1 per cent. analogue. All the values for the leukaemic mice were higher than for the non-leukaemic.

When groups of normal mice were given intraperitoneally a dose of one million lymphatic cells from leukaemic mice, and were maintained on Purina chow or on the experimental diet with 0.75 per cent. analogue, there was no difference in their survival time.

When mice of the leukaemic strain were maintained on Purina chow or on the experimental diet with 0.75 per cent. analogue, there was no difference in the incidence of leukaemia, but the analogue gave a slight increase in mean survival time.

The lack of effect of the ascorbic acid analogue on lymphocytic anaemia was considered to be due probably to the biosynthesis of sufficient ascorbic acid for conversion of folic acid to citrovorum factor.

Cortisone acetate reduced the incidence of spontaneous leukaemia in mice, whether receiving Purina chow or the experimental diet; on the latter with 0.75 per cent. D-glucoscorbic acid the effect was greater.—A. Hepburn.

544

PINO, A. and FERRACUTI, B. Au sujet des variations de la teneur en protéines, vitamine C et lactose dans le lait de chèvres traitées avec "Helichrysrum Italicum G. Don." [Variations in the content of protein, vitamin C and lactose in the milk of goats given *Helichrysrum italicum*, G. Don.] *Lait*, 1954, 34, 369-388.

After a preliminary period of 8 days, 3 adult lactating goats were treated for 30 days with equivalent amounts of different preparations of the plant *Helichrysrum italicum*. Two preparations were aqueous and the third was a syrup. The animals remained healthy and their weight and milk production did not vary. Analysis of the milk for protein, ascorbic acid and lactose before and after treatment showed no significant differ-

ence between the goats. Protein values fluctuated and rose to a maximum after about 26 days' treatment with an increase of about 26 per cent. Ascorbic acid rose to a secondary peak after 10 days' treatment before reaching a maximum at the same time as protein with an increase of about 180 per cent. Both then fell but to a value higher than the original. Lactose fluctuated widely and decreased on the whole throughout the experiment to reach a minimum 2 days after the end of treatment with a decrease of about 11 per cent.

A. Hepburn.

545

SOKOLOV, F. Obogashchenie sgyschennogo moloča s sakharom askorbinovoi kislotoi i vitaminom A. [Enrichment of sweetened condensed milk with ascorbic acid and vitamin A.] *Mol. Prom.*, 1954, 15, No. 1, 34-35. [Latvian Agric. Acad.]

The addition of from 200 to 500 mg. ascorbic acid per kg. condensed milk formed a product of good quality, with great vitamin activity and stability during 9 months' storage at low temperatures. When more than 2 mg. vitamin A was added to the milk, the taste deteriorated. It is recommended that the ascorbic acid should be added as an aqueous solution.—H. Scherbatoft.

546

DJORDJEVIĆ, N. Vitamin C u žiru (semen *Quercus*). [Vitamin C in the acorn.] *Acta vet.*, Belgrade, 1954, 4, No. 2, 49-51. [Inst. Pharmacol.] English summary.

Ascorbic acid was estimated by indophenol titration. In the mature acorn the maximum content was 54.8 mg. per cent. During storage there was a gradual decrease and 40 per cent. only of that originally present was found after 2½ months. (From summary.)—A. Hepburn.

547

WISHART, J. W. Ascorbic acid (vitamin C) content of varieties of blackcurrants. *Tasmanian J. Agric.*, 1954, 25, 164-167. [Govt. Analyst's Lab., Hobart.]

Studies over 6 seasons showed considerable differences in ascorbic acid content between varieties of black currant grown in Tasmania; White Bud was consistently best and Goliath worst, with 390 and 220 mg. per 100 g. fruit, respectively, in 1954. Such variety differences should be remembered in selecting black currants for juice manufacture. In any one variety there was no differences between early and late maturing berries, but, as was found by Oliver (Abst. 485, Vol. 8), the smaller fruits had a higher ascorbic acid content than the larger.

Ascorbic acid was estimated by the potentiometric method of Harris *et al.* (Abst. 1146, Vol. 12) or that of Liebmann and Ayres (Abst. 3251, Vol. 15).—W. M. Deans.

548

PAUL, P. and FERLEY, M. **Palatability and ascorbic acid content of broccoli frozen under different conditions.** *Food Res.*, 1954, 19, 272-275. [Dept. Food Nutrit., Michigan State Coll.]

Ascorbic acid was estimated in samples of broccoli exposed, wrapped in cellophane, and in the final boxed state, and then frozen in still and in moving air; the temperature was recorded by thermocouples. Different rates of freezing were thus obtained, and the broccoli was tested after 1 week, and after 3, 9 and 13 months' storage.

Flavour, appearance, texture and palatability were not significantly affected by the rate of freezing but with the slower rate of freezing in packaged material, the ascorbic acid content was less. The length of storage had no effect on the ascorbic acid content.—A. Hepburn.

549

HUGGART, R. L., HARMAN, D. A. and MOORE, E. L. **Ascorbic acid retention in frozen concentrated citrus juices.** *J. Amer. Dietetic Assoc.*, 1954, 30, 682-684. [Florida Citrus Exp. Stat., Lake Alfred.]

Freshly frozen concentrates of juice from 3 different varieties of orange, 2 of grapefruit and one of tangerine were stored at temperatures of -8° , 10° , 20° , 32° and 40° F., and ascorbic acid was estimated by indophenol titration initially, after 1 and 2 weeks, and at intervals up to 12 months.

After 12 months at -8° F. the concentrates

showed an average retention of ascorbic acid of slightly over 98 per cent., less at higher temperatures, down to 95 per cent. at 40° F. The tangerine concentrate had the lowest percentage retentions, 94 and 89.7 per cent. at -8° and 40° F., respectively.

After storage for from 15 to 18 months, the juices were reconstituted by diluting 25 ml. of the concentrate with 75 ml. water; they were then stored for 2 days in a refrigerator at 50° F. The percentage retention of ascorbic acid in the reconstituted juices was over 94 for orange and grapefruit juice and over 91 for tangerine juice.

A. Hepburn.

552

LECOQ, R., CHAUCHARD, P. and MAZOUÉ, H. **Étude chronaximétrique de l'avitaminose P et des facteurs vitaminiques P. [Study of vitamin P deficiency and vitamin P factors by measurement of chronaxie.]** *Ann. pharm. franç.*, 1954, 12, 179-190. [Hôp. St.-Germain-en-Laye, École Hautes-Études, Paris.]

Lack of vitamin P was easily demonstrated by measurement of nervous chronaxie. The condition is thought to be due to acidity for it was counteracted by giving preparations likely to promote alkalosis such as hesperidose, rutoside, epicatechin and leucocyanidol.—K. H. Coward.

553

ZAPROMETOV, M. N. **O vitamine, ukreplyayushchem stenki krovenosnykh kapillyarov. [The vitamin which strengthens the capillary walls.]** *Priroda*, 1954, No. 2, 103-106. [A. N. Bakh Inst. Biochem., Acad. Sci. USSR.]

One of the most active materials for strengthening the capillary walls was found to be the catechins of tea, present in the fresh leaves and in green tea. Vitamin P can be extracted from the rough leaves of tea which are useless in the tea trade. Subcutaneous injection of a preparation of catechins considerably increased the resistance of the capillary walls in white mice. The complex preparation of catechins from tea leaves (so-called tea tannin) has the effect of regulating the activity of the thyroid gland.

In human beings daily doses of from 100 to 150 mg. tea tannin established normal resistance of the capillaries in a few weeks even in deep-seated haemorrhages. It was a means also of healing trophic ulcers. The production of vitamin P from tea leaves is now being undertaken by the food industry.—H. Scherbatoff.

ENZYMES

554

GÓMEZ, F., RAMOS GALVÁN, R., CRAVIOTO, J. and FRENK, S. Estudio sobre el niño desnutrido. 11. Actividad enzimática del contenido duodenal en niños con desnutrición de tercer grado. [Studies on the undernourished child. 11. Enzymic activity of the duodenal contents in children affected with third degree malnutrition.] *Pediatrics*, 1954, 13, 544-548 (in English, 548-552). [Serv. Nutrición, Hosp. Infantil, Mexico.]

The study included 40 children between 5 months and 7 years old with "third degree malnutrition", i.e., showing delayed growth, skin changes, dyspigmentation, oedema, anaemia, liver changes, low protein levels in serum and spinal fluid, anorexia, apathy and periodic diarrhoea. Samples of duodenal contents were obtained by Levin tube and tested for amylase, trypsin and lipase activity, within 5 days after admission to hospital and again shortly before discharge.

All 3 enzymes were much below normal at the initial sampling and rose towards normal as the children recovered. There was no statistical correlation between enzyme levels and anorexia or diarrhoea. Absorption of protein appeared to be slow in early stages of treatment.—D. Duncan.

555

ROSENTHAL, O. and VARS, H. M. (with NOVACK, B. G. and ZERBE, J. W.) Response to fasting of hepatic arginase, alkaline phosphatase, and rhodanese in protein-depleted rats. *Proc. Soc. Exp. Biol. Med.*, 1954, 86, 555-558. [Harrison Dept. Surg. Res., Sch. Med., Univ. Pennsylvania, Philadelphia.]

Male rats fed on a protein-free diet for 2 weeks were fasted for 2 or 4 days and then killed. Arginase in the liver increased by 20 and 58 per cent. after 2 and 4 days; alkaline phosphatase decreased by 7 and 58 per cent. Rhodanese increased by 26 per cent. after 2 days and then no further.

The initial increase in arginase content was of an order similar to that of rhodanese, a functionally unrelated enzyme, and to the total protein. This was considered a non-specific response due to an increase in hepatic protein. The more significant increase in arginase after 4 days and the decrease in alkaline phosphatase were considered specific and probably related to the increased protein metabolism.—A. Hepburn.

556

RAMACHANDRAN, S. and SARMA, P. S. Rôle of inositol in the activity of alpha-amylase. *Indian J. Med. Res.*, 1954, 42, 201-209. [Biochem. Lab., Univ. Madras.]

Rats given 2 or 5 mg. of the γ -isomer of hexachlorocyclohexane per 100 g. diet had, by the end of 10 to 12 weeks, all developed alopecia, but others given supplements of inositol showed no alopecia. No difference was found between the weights of the groups. The amylase activity of plasma and of pancreas was higher in the group with than in the group without inositol. In a rabbit given 250 mg. of the isomer at the rate of 25 mg. on alternate days amylase activity in blood was lower than in a control animal; in one of 2 others receiving the isomer 100 μ g. biotin had no restoring effect, but in the other 2500 mg. inositol maintained the activity at a level near normal. Further work with larvae of the rice moth, *Corcyra cephalonica*, showed that the reduction of their amylase activity caused by the γ -isomer could be prevented by giving them inositol; this contradicted the earlier finding by one of the authors (Sarma, *Current Sci.*, 1950, 19, 315) that inositol had no such effect.

Experiments *in vitro* showed that the inhibiting effect of the γ -isomer on synthesis and secretion of amylase by slices of pigeon pancreas was limited by both inositol and biotin to an extent which increased with their concentrations. This effect of biotin was studied also in rats and rice moth larvae with induced biotin deficiency. The presence or absence of biotin was without effect on the amylase activity of the plasma or pancreas of the rats or of the tissue of the larvae. It is suggested that in the pancreas slices the biotin acted indirectly by stimulating synthesis of inositol.

inolitica e la malattia aterosclerotica sperimentale: ricerca sul ruolo antiateromassico dell'ATP. [Tributyrin-splitting lipase and experimental atherosclerosis; research on the role of ATP against atheroma.] *Acta gerontol.*, 1954, **4**, 89-96. [Ist. Patol. Med., Univ. Bari.] French and English summaries.
- Rabbits received cholesterol in olive oil in doses of 1 g. daily for 50 days or 0.5 g. for 140 days and the experimental animals, but not the controls, received 2.5 mg. adenosine triphosphate (ATP) daily by vein or subcutaneously or 1 mg. by vein. Finally all were killed and the tributyrin-splitting activity was estimated of serum, liver, kidney and in one experiment of intestine.
- In serum the enzyme activity in groups treated with ATP was always greater than in controls. The greatest protection against the effects of cholesterol on liver and kidney was obtained when ATP was given subcutaneously, and in these animals enzyme activity of liver and kidney was low. ATP had no effect on the intestinal enzyme.

STOVNER, J. and LIND, B. Succinylcholinapne og serumcholinesterase. [Apnoea caused by succinylcholine, and serum cholinesterase.] *Nord. Med.*, 1954, **52**, 1223-1225. [Rikshosp., Oslo.] English summary.
- Succinylcholine is destroyed by serum cholinesterase (pseudocholinesterase). Prolonged apnoea after relatively small amounts of succinylcholine has been shown to be associated with low values of serum cholinesterase. Six further cases are described. In 5 of them serum cholinesterase was inversely related to the duration of apnoea. Blood transfusion may shorten the apnoea, since the enzyme survives in the blood bank.—I. Leitch.

McLEAN, J. R. and BEVERTIDGE, J. M. R. Hepatic necrosis induced by dietary means. 7. The effect of a necrogenic diet on plasma pseudocholinesterase levels in the rat. *Rev. canad. Biol.*, 1953, **12**, 1-5. [Dept. Biochem., Queen's Univ., Kingston, Ont.] French summary.
- For other parts see Absts. 2269, Vol. 22; 749, Vol. 23; 4827, Vol. 24.
- The value of plasma cholinesterase concentration as criterion for early assessment of the necrogenic properties of a diet was examined. Thirty-three pairs of rats weighing about 105 g. were given a necrogenic diet containing, per cent., primary grown yeast 18, lard 5, maize starch 69, salts 3, Cellu flour 2, cod liver oil 2, and sugar vitamin mixture 1. Each rat received about 8 g. diet, and one of each pair had 4 mg. α -tocopherol incorporated in it. Pairs of rats were killed from 15 to 49 days later and pseudocholinesterase in the plasma was estimated by the method of Mendel *et al.* (Abst. 2827, Vol. 13).
- Among 27 pairs the value was lower in 16 rats not given tocopherol, higher in 3 given tocopherol, and the same in 8 pairs. The variation was too great for a single estimation to be used to assess the necrogenic potency of a diet.—E. M. Hume.

RICHERT, D. A. and WESTERFELD, W. W. The relationship of iron to xanthine oxidase. *J. Biol. Chem.*, 1954, **209**, 179-189. [Dept. Biochem., Med. Coll. State Univ. New York, Syracuse.]
- For earlier work see Absts 4940, 4941, Vol. 21; 858, Vol. 24.
- The omission from the purified diet of Mn, Cu or Zn had no effect on the xanthine oxidase

response to Mo, but omission of Fe reduced the response. Both Fe and Mo are thus required for formation of intestinal xanthine oxidase. Increasing the intake of Cu or Zn to 10 times the normal or that of Mn to 20 times had no effect on the response.

Rats fed on fresh milk showed only a partial response of intestinal xanthine oxidase to Mo, but maximum response to Mo + Fe. In the absence of Fe addition of Cu or Mn reduced the response to Mo. Liver xanthine oxidase was not affected by the presence or absence of Fe, Cu or Mn in the diet, except that in absence of Fe it was increased by Cu. Similar but smaller responses were obtained with a purified casein diet.

Xanthine oxidase prepared from fresh raw cream and dialysed gave atomic Fe:Mo ratios between 8 and 10. Two riboflavin molecules were present in the enzyme for each atom of Mo. The minimum molecular weight was estimated as about 320,000. No evidence of porphyrin structure was found.

Absorption spectra showed that Fe accounts for at least part of the hitherto unidentified component in the spectrum of xanthine oxidase.

The enzyme was not inhibited by Versene, $\alpha\alpha$ -dipyridyl or sodium azide, and Fe did not reactivate it after inhibition by KCN.—D. Duncan.

VAN WAYJEN, R. G. A., GROEN, J., KUIJZER, P. J. and WILLEBRANDS, A. F. Voeding, resorptie en stofwisseling bij patiënten na totale maagresectie. [Diet, absorption and metabolism of patients after complete removal of the stomach.] *Nederl. Tijdschr. Geneesk.*, 1954, **98**, 2048–2060. [2. Clin. Inw. Ziekten, Wilhelmina Gasthuis, Amsterdam.] English summary.

Details are given for 10 patients of the energy value of food eaten and of N and fat balances; for 8 of the patients from 23 to 72 days after operation, for the other 2, after 11 months and 11.5 months. Weight and basal metabolic rates are also recorded. Absorption of protein and fat was poor and could not be improved by giving folic acid, liver preparations or vitamin B₁₂. But when small meals were taken frequently the patients gained on the average 4 kg. weight during the study, which lasted about 30 days.—I. Leitch.

576

WIRTS, C. W., REHFUSS, M. E., SNAPE, W. J. and SWENSON, P. C. Effect of tea on gastric secretions and motility. *J. Amer. Med. Assoc.*, 1954, **155**, 725–729. [Dept. Med., Jefferson Med. Coll., Philadelphia, Pa.]

The effect of tea and of water on pH and pepsin of gastric juice obtained from 10 fasting subjects without gastric disease was studied *in vitro*. Over 100 patients with gastro-intestinal disease were used in studies of the effects of tea and of water on pH, pepsin and gastric emptying time and in studies of gastric motility with intragastric balloons and X-ray.

The results indicate that tea stimulates gastric motility, but has approximately the same effect as water on gastric secretion. It would seem that tea may be allowed as a beverage in average amounts in the treatment of most gastro-intestinal conditions.—F. C. Aitken.

KIRILUK, L. B. and MERENDINO, K. A. An experimental study of the buffering capacity of the contents of the upper small bowel. *Surgery*, 1954, **35**, 532–537. [Dept. Surg., Sch. Med., Univ. Washington, Seattle.]

In adult dogs both pH and buffering capacity of intestinal secretions, as estimated by lavage of consecutive 10-cm. sections of the small intestine with intact blood supply, decreased from the pylorus to the fifth section and rose again in the eighth. The range of pH was approximately 7.30 to 7.15. Buffering capacity decreased all the way. I. Leitch.

582

FRAZER, A. C. Fatty acid absorption and chylomicrons.

SINGER, H., SPORN, J. and NECHERLES, H. Fatty acid absorption and chylomicrons. *Science*, 1954, **120**, 39; 39–40. [Med. Sch., Hosp. Centre, Birmingham.]

Frazer earlier (Abst. 745, Vol. 16) concluded that saturated fatty acids were partitioned between the oil and water phases in the intestine "according to chain length and water-solubility and that this differential distribution affected their absorption". Later isotopic studies in the United States confirmed these observations. The absorption of unsaturated fatty acids depends on whether they are taken in the free state or as glyceride esters; no intraluminal emulsification occurred with free oleic acid, though significant amounts were absorbed: under different circumstances it is admitted that oleic acid may undergo emulsification.

Singer, Sporn and Necheles "do not doubt the general truth of the partition hypothesis of fat absorption", but consider that some of their experiments may modify it. Intraluminal emulsification occurred when oleic acid was introduced into a Thiry loop of intestine, although bile and pancreatic juice were absent; the number of chylomicrons was equal to that found after oral administration of oleic acid at 0.5 g. per kg. bodyweight.—G. A. Garton.

583

HEWITT, W. A histochemical study of fat absorption in the small intestine of the rat. *Quart. J. Microscop. Sci.*, 1954, 95, 153-157. [Dept. Anat., Univ. Liverpool.]

Male albino rats weighing 190 to 233 g. were starved for 48 hr. but allowed free access to water. Each animal then received 225 mg. triolein by stomach tube. The rats were killed 2½ hr. later and sections of intestine were removed and examined with Sudan black and the acid haematin test with and without Sudan red colouration. Details are given of the histochemical appearance of the epithelial cells of the mucous membrane. Lipid was observed within the epithelial cells and their free border and it also occurred as particles between the cells. It is concluded, therefore, that triolein is absorbed not only by passing through the epithelial cells of the intestinal mucosa, but also by passing between these cells.

G. F. Garton.

DONNET, V. and GARNIER, L. Absorption intestinale des solutions de chlorure de sodium. [Absorption from the intestine of sodium chloride solutions.] *C.R. Soc. Biol.*, 1954, 148, 549-551.

Experiments were made on 2 dogs with Thiry Vella loops; one had also most of the thyroid removed. The loops were perfused with NaCl solutions at concentrations from 1 to 18 per thousand, at 20 ml. per min.

In both dogs the greatest absorption was at concentrations of 4 to 5 per thousand. The curve of absorption showed a linear relation between absorption and concentration, but the relation was inverse at concentrations above 16 per thousand.—D. Duncan.

585

EJARQUE, P. and JIMÉNEZ-VARGAS, J. Sobre la absorción intestinal de cloro. [Absorption of chlorine from the intestine.] *Rev. española Fisiol.*, 1953, 9, 243-256. [Inst. Fisiol., Fac. Med., Barcelona.] English summary.

Chloride absorption was studied in rats by the Sols and Ponz technique (Abst. 1663, Vol. 18), with solutions of 0.3, 0.9 and 1.5 per cent. NaCl and a

constant pressure of 20 cm. water. Absorptions lasted 30 min. and were repeated after washing out the segment with isotonic glucose solution.

With the hypotonic solution chloride secretion exceeded absorption, but with the isotonic and hypertonic solutions chloride was absorbed, more rapidly from the latter. Differences in secretion and absorption between loops of jejunum and of ileum were slight.

The mechanism of chloride absorption is discussed.—D. Duncan.

586

WEISS, K. E. Physiological studies on eructation in ruminants. *Onderstepoort J. Vet. Res.*, 1953, 26, No. 2, 251-283. [Onderstepoort Lab.]

A study of the relation of eructation to rumen contractions showed that belching occurred immediately after the secondary rumen contraction and that the occurrence of the secondary contraction was erratic. After the introduction of air into the rumen its incidence was increased.

The efficiency of belching was estimated by the time taken for air introduced into the rumen to be removed, as judged by the time taken for the pressure within the rumen to fall to its initial level. The introduction of alkali into the rumen, abdominal vagotomy, or distension of the abomasum or caecum all reduced the efficiency of belching, principally by inhibition of contractions of the reticulum. Drugs inhibiting movements or causing spasms of the rumen similarly reduced the efficiency of belching.—A. T. Phillipson.

587

DOWNIE, H. G. Photokymographic studies of regurgitation and related phenomena in the ruminant. *Amer. J. Vet. Res.*, 1954, 15, 217-223. [Dept. Physiol., New York State Vet. Coll., Cornell Univ., Ithaca.]

From a steer and 2 cows records were made of intranasal and intratracheal pressure, bolus movement in the oesophagus, abdominal movement, jaw movement and time. The records were made on a photokymograph with a series of segment capsule manometers and a variac transformer, with a straight filament bulb as source of light.

The method gave a precise picture of the pressures involved in regurgitation. Negative intratracheal pressures ranged from 120 to nearly 300 mm. bromoform. If a regurgitation failed to aspirate sufficient ingesta, a second attempt followed, with increased negative pressure, at the height of the rumen contraction. Positive pressure often preceded and followed the negative pressure, a plateau being maintained until the glottis opened.

The tracings also permitted accurate assessment

of the time taken by each stage of the process of regurgitation, and data were collected on the number and frequency of the jaw movements involved. Other recordings indicated that when the negative pressure of regurgitation is sustained the flow of blood to the heart from the jugular veins is significantly increased.—W. A. Greig.

588

WEISS, K. E. The significance of reflex salivation in relation to froth formation and acute bloat in ruminants. *Onderstepoort J. Vet. Res.*, 1953, 26, No. 2, 241-250. [Onderstepoort Lab.]

The consistency of rumen contents was compared by measuring the weight and time necessary to draw a mercury-weighted bulb through a measured distance in the contents.

When Merino sheep were fed on alfalfa in the flowering or pre-flowering stage, the consistency of digesta was always greater with the preflowering stage. A high index was related to the incidence of bloat.

The speed at which air, introduced into the rumen by bubbling it through the contents, was removed by belching was measured by the time needed for the pressure in the rumen to return to its initial level. This took longer when pre-flowering alfalfa was eaten, presumably owing to foam formation. Mechanical distension of the rumen with trapped gas is considered to be concerned in producing bloat, but in contrast it is also stated that the presence of saponins in alfalfa contributes towards the colloidal state of the contents.—A. T. Phillipson.

589

DALE, H. E., STEWART, R. E. and BRODY, S. Rumen temperature. 1. Temperature gradients during feeding and fasting. *Cornell Vet.*, 1954, 44, 368-374. [Dept. Vet. Physiol., Univ. Missouri, Columbia.]

The subject was a 3-year-old Jersey heifer neither pregnant nor lactating. Thermocouples soldered to a long probe were introduced into the rumen through a stab wound.

The rumen temperature was always higher than the rectal temperature, by about 4° F. under normal feeding conditions but by only 1.5° F. after a 24-hr. fast. The rumen showed a temperature gradient with the highest temperature at the uppermost thermocouple, nearest the most recently eaten material, except immediately after eating, when the temperatures fell most at the top and bottom of the rumen. When 14 lb. water at 62° F. was pumped into the rumen by a stomach tube the temperature rose in 2 phases, a rapid increase probably caused by mixing, and a slower warming of the chilled ingesta. The rectal temperature remained constant.—D. Duncan.

590

NANGERONT, L. L. Variations in intraruminal temperatures of sheep during normal and abnormal conditions. *Cornell Vet.*, 1954, 44, 403-416. [Dept. Physiol., New York State Vet. Coll., Ithaca.]

Four adult wethers weighing 100 to 120 lb. were provided with rumen cannulae. Temperatures in the rumen were recorded by a copper-constantan thermocouple, and in the rectum by a thermocouple or a clinical thermometer.

When sheep drank water the rumen temperature dropped, and the magnitude and duration of the drop were proportional to the amount of water. When alfalfa hay was eaten the temperature rose by 0.2° to 0.8° C., and clover hay gave increases of as much as 1.2° C. The rumen temperature was relatively constant during fasting. When sheep were allowed to eat a dairy ration with 16 per cent. protein to appetite, usually about 1 kg., the average rise in temperature was 0.6° to 0.8° C. When larger amounts were placed in the rumen through the cannula there was not a proportionately greater increase in temperature. Large quantities of freshly cut alfalfa either eaten or ground and introduced by the cannula lowered the temperature.

Introduction of pure oxygen into the rumen did not affect the temperature unless the volume was sufficient to cool the ingesta. Introduction of powdered glucose caused the temperature to rise by 0.5° to 1.0° C. unless water was available, but if allowed to do so the sheep would drink and the temperature then fell.

Toxic quantities of new wheat or rye, which killed one sheep and made another very ill, did not increase the rumen temperature more than did normal feeds.—D. Duncan.

591

CHAIGNEAU, M. and CHARLET-LÉRY, G. Composition des gaz de digestion chez les ruminants. [Composition of gases arising from digestion in ruminants.] *C.R. Acad. Sci.*, 1954, 239, 308-310.

Two sheep were fed on alfalfa hay and apple residues and direct samples of intestinal gases were taken by a tube inserted into the anus. A third sheep fed on alfalfa hay had a direct sample of the rumen gases taken by fistula 15 hr. after the last feed.

The mean contents of intestinal gases in volumes per cent. were CO₂ 9.8, CH₄ 51.3, N 39.0, and for rumen gases 34.0, 19.7 and 39.2, respectively, with oxygen 7.1. Ethane was not found in gases from either source.—A. Hepburn.

592

ANNISON, E. F. Some observations on volatile fatty acids in the sheep's rumen. *Biochem.*

N.A. and R., January 1955

J., 1954, **57**, 400-405. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]

The gas/liquid partition chromatogram was used to estimate volatile acids in the rumen contents of sheep fed on rations rich in protein or starch and on hay.

On all diets the proportions of acids present in the rumen decreased as the length of the hydro-

carbon chain increased; isobutyric, isovaleric and 2-methylbutyric acids were present, the latter in the dextro-rotatory form. Formic acid was occasionally found in traces and an unidentified C_6 acid was found when the sheep were starved. Branched-chain isomers were present in smaller quantities than n -acids.—A. T. Phillipson.

595

JORDAN, P. Some notes on the haemoglobin levels of infants in the first year of life. *East African Med. J.*, 1954, **31**, 143-145. [E. African Med. Survey, Mwanza.]

Hb was estimated with the Medical Research Council grey-wedge photometer standardised to read 14.8 g. Hb per 100 ml. blood (100 per cent. Haldane). Hb values for 44 Wasukuma mothers just before parturition and for their infants at birth showed no correlation. It is the native custom not to cut the cord till after delivery of the placenta. The mean values on the first day for Hb, red cells and haematocrit, respectively, were for 10 infants thus treated 20.6 g., 5.5 million, and 60, and for 10 infants whose cord was clamped immediately, 16.4 g., 4.8 million, and 52. On the third day the reticulocyte count was 5.9 in the first and 2.9 in the second group.

Hb values estimated monthly up to 12 months of age showed a course not unlike that of London children, falling from 145 per cent. (Haldane) at birth to just over 70 per cent. at and after 3 months. In infants with malaria the course was similar, but at a lower level.—E. M. Hume.

596

ITANO, H. A., BERGREN, W. R. and STURGEON, P. Identification of a fourth abnormal human hemoglobin. *J. Amer. Chem. Soc.*, 1954, **76**, 2278. [California Inst. Technol., Pasadena.]

Vol. 25, No. 1

Electrophoresis on filter paper of haemoglobin from a child with atypical anaemia revealed the presence of 2 components, one with the mobility of haemoglobin F and the other with mobility nearly that recorded for haemoglobin C. The haemoglobin, more detailed study of which will be reported, is considered to be a mixture of haemoglobin F and of a haemoglobin, hitherto undescribed, which it is proposed to call haemoglobin E.—D. Harvey.

597

EDINGTON, G. M. and LEHMANN, H. Haemoglobin G. A new haemoglobin found in a West African. *Lancet*, 1954, **267**, 173-174. [Med. Res. Inst., Accra, Gold Coast.]

A sample of Hb from a West African man was found by paper electrophoresis at pH 8.6 to separate into the normal variety A and another which migrated faster than the sickle-cell variety S. Agglutination tests excluded the foetal variety F. The only other with a similar migration rate is Hb D but, in the Tiselius apparatus, its behaviour has been reported (Itano, *Science*, 1953, **117**, 89) as identical with that of S. The new alphabetical designation Hb G is accordingly proposed.—D. Harvey.

598

GARRY, R. C., SLOAN, A. W., WEIR, J. B. DE V. and WISHART, M. The concentration of haemoglobin in the blood of young adult men and women: the effect of administering small doses of iron for prolonged periods. *Brit. J. Nutrition*, 1954, **8**, 253-268. [Inst. Physiol., Univ. Glasgow.]

The literature dealing with the Hb content of blood of adult man and of mature lower mammals is reviewed. In women the Hb content of the blood is known to be less than that in men, but evidence for this sex difference is not well established in lower mammals.

Two series of experiments were made on the Hb content of the blood of male and female university students whose ages and general environment were similar. In the first series the mean value for 24 men was 15.92 ± 0.23 g. Hb per 100 ml.

blood and that for 41 women was 14.20 ± 0.13 . The women were given a supplement of 7 mg. Fe daily for 5 months; the men received no Fe. The mean Hb content of the blood increased slightly in both the women and the men, so that there was no satisfactory evidence that small doses of Fe increase the Hb content of the blood of women.

In the second series the mean Hb content for men was 16.21 ± 0.11 g. Hb per 100 ml. blood and that for 55 women was 14.59 ± 0.10 . The men and women were divided each into 3 groups; one group of each sex received a supplement of 28 mg. Fe as ferrous sulphate together with 0.52 mg. copper sulphate and 0.47 mg. manganese sulphate; one group of each sex received a supplement of 14 mg. Fe with 0.26 mg. Cu and 0.24 mg. Mn and the remaining 2 groups acted as controls and received similar tablets containing no Fe, Cu or Mn. The tablets were taken for 1 year. After this time the difference between the mean Hb contents of the blood of men and women was still about 1.5 g. Hb per 100 ml. blood; administration of Fe had failed to decrease the difference, which could not, therefore, be attributed to lack of Fe in the women's diets. Relatively to the control groups the men and women who received Fe showed an increase in the Hb content of the blood. In both sexes, also, the lower the initial Hb value the greater was the response to Fe.

GARROW, J. S. Some haematological and serum protein values in normal Jamaicans. *West Indian Med. J.*, 1954, 3, 104-107.

The haematological investigations were of Hb, packed cell volume, mean corpuscular Hb concentration (MCHC), red cell sedimentation rate, total protein, albumin and globulin in serum, and the subjects were healthy, well nourished and apparently normal undergraduates and laboratory technicians. The numbers of persons and the mean values for the sexes were, males: Hb, 126, 14.90 g.; packed cell volume, 76, 46.1 per cent.; MCHC, 76, 30.0 per cent.; sedimentation rate, 49, 8.2 mm. per hr.; total protein 112, 7.28 g.; albumin, 112, 3.90 g. and globulin, 112, 3.37 g. per 100 ml. For females corresponding numbers and means in the same order were: 79, 12.66; 48, 41.7; 48, 30.1; 48, 19.5; 67, 7.17; 67, 3.79 and 67, 3.37. The MCHC and albumin:globulin ratio are low in comparison with United Kingdom and Canadian standards.—D. Harvey.

THOMAS, J. W., OKAMOTO, M., JACOBSON, W. C. and MOORE, L. A. A study of hemoglobin levels in the blood of young dairy calves and the alleviation of anemia by iron. *J. Dairy Sci.*, 1954, 37, 805-812. [Dairy Husb. Res. Branch, U.S. Dept. Agric., Beltsville, Md.]

Holstein, Jersey, Red Danish, crossbred and Sindhi \times Jersey cross calves, in all 365 animals, were used. Hb values were estimated weekly or fortnightly from birth to 105 days of age.

Hb values were highest at birth and lowest at 40 to 60 days of age, after which they tended to increase coincidentally with increased consumption of alfalfa hay. Hb values of Jersey and Holstein calves were lower than those of crossbreds, Red Danish or Sindhi \times Jersey crosses. In breeds in which there were sufficient numbers of calves of both sexes available for comparison, females had higher Hb values than males. Supplements of Fe alone or with Cu, Co and Mn significantly increased Hb values. Cu, Co and Mn without Fe had no effect. When the bodyweight gains of Holstein and Jersey calves were expressed as a percentage of the normal for the respective breeds, calves with the highest percentage gains had higher Hb values than those with lower gains.

TANAKA, T. and ROSENBERG, M. M. Relationship between hemoglobin levels in chickens and certain characters of economic importance. *Poultry Sci.*, 1954, 33, 821-827. [Dept. Poultry Husb., Univ. Hawaii, Honolulu.]

New Hampshire chickens were given an adequate starter ration up to 6 weeks of age, grower's rations to 12 weeks and thereafter laying rations. All chickens received fowl pox vaccine at 4 weeks of age, and formalin-inactivated Newcastle vaccine at 6 weeks and again at 18 weeks. After 18 weeks the birds were housed individually and received artificial light for 14.5 hr. daily.

In order to study the effect of age on Hb value, 3 chickens from each of 40 dams were selected at hatching and reared as above to 80 weeks of age. There was no difference in blood Hb value between males and females until 8 weeks of age; thereafter the males were the higher, with 9.81 g. Hb per 100 ml. blood on the average compared with 8.92 g. Hb per 100 ml. for females. The Hb value in the males increased steadily to the forty-sixth week, when it began to vary irregularly. The Hb value of females increased slowly from the eighth

to the twentieth week and then fell by 1.67 g. per 100 ml. blood by the twenty-second week; many pullets matured during this period. A gradual decrease continued to the twenty-eighth week, followed by a gradual rise to the fortieth, whereafter the value was constant. The average Hb level from the twenty-fourth to the eightieth week of age was 13.19 ± 0.73 g. per 100 ml. for males and 8.61 ± 0.29 for females.

In the second experiment, 310 laying pullets and 59 non-laying, either moulting or pausing, pullets were used; the mean Hb values were 8.07 g. and 8.55 g. per 100 ml., respectively. The Hb value for 34 hens in production was 8.13 and for 33 non-laying hens 8.67 g. The group differences between laying and non-laying were not significant. Of the non-laying pullets 52 were bled 10 weeks later when in lay and gave a value 0.33 g. per 100 ml. lower than their previous value, a statistically significant difference. A more detailed study on fewer birds indicated that Hb values increased 2 weeks before the onset of pause and reached a peak 2 weeks after egg production resumed; thereafter a gradual decrease was found.

It was shown that Hb values and bodyweight at 6, 12, 18 or 24 weeks or 10 months of age were not correlated, in contradiction to a previous unpublished study. There were non-significant correlations between Hb values and age at sexual maturity and persistency of production.

RODECK, H. and RÖTTGER, H. Plasmavolumen und extracelluläres Gewebsswasser im Laufe der Entwicklung des Kindes. [*Plasma volume and extracellular tissue water in the growing child.*] *Ztschr. Kinderheilk.*, 1954, **74**, 610-621. [*Kinderklin., Med. Akad., Düsseldorf.*]

Plasma volume was estimated with Geigy Blue and extracellular tissue water by the Na thio-cyanate method in 106 healthy children of ages and stages of development from birth to 17 years. With increase of bodyweight there was a continuous increase in the absolute volumes of plasma and tissue water, but the reverse was true for the relative values. The percentage of plasma and tissue water referred to bodyweight was very high in children of low weight, but decreased more and more with increasing weight. The absolute amount of plasma increased from about 350 ml. at 5 kg. to about 2400 ml. at 63 kg., and the relative values for the same weights fell from 7 to 3.7 per cent. Similarly tissue water volume increased from 2000 ml. to 13,000 ml., and the relative values fell from 40 to 21.4 per cent. of bodyweight. Up to puberty no difference was found between the sexes, but after puberty the boys showed absolutely and relatively greater plasma volume and extracellular tissue water volume than the girls, though owing

to the smallness of the groups at this stage the difference was not significant. Five children with pre-puberty adiposity had a higher absolute water content than normal children of the same age, but the relative value was less. The big increase of weight in this disease is to be attributed much more to increased fat than to increased water storage.—M. B. Richards.

604

ELLIS, B. C. A comparison of the T1824 blood volume at sea-level and an altitude of 5,740 feet in normal South African European males. *S. African J. Med. Sci.*, 1954, **19**, 11-14. [*Dept. Clin. Pathol., Univ. Witwatersrand, Johannesburg.*]

Twenty healthy male medical students between 20 and 24 years of age and living at sea level in Cape Town were subjects for comparison with earlier work (Abst. 1924, Vol. 24) in Johannesburg at an altitude of 5740 ft. Mean values for the data, with standard deviations, were: height 180 ± 7.39 cm., weight 70.4 ± 8.17 kg., plasma volume 3060 ± 384.1 ml., total blood volume 5630 ± 722.8 ml., red cell volume 2570 ± 370.8 ml., venous packed cell volume 47.5 ± 2.10 per cent. In comparison with sea-level data from elsewhere these volumes, expressed in ml. per kg., plasma 43.5, total blood 80.1, and red cell 36.6, were within the normal range. In comparison with the Johannesburg values differences were statistically significant only when expressed as ml. per kg.; at altitude plasma and total blood volumes were, respectively, 9.7 and 6.2 per cent. lower than at sea level and red cell volume was no different. These findings support the view that, at moderate altitude, reduction of plasma volume causes haemoconcentration which compensates for the associated relative anoxia.—D. Harvey.

605

CRONIN, M. T. I. The determination of plasma volume and the estimation of blood volume in the horse. *Vet. Rec.*, 1954, **66**, 197-200. [*Animal Health Trust Equine Res. Stat., Newmarket.*]

A healthy 4-year-old thoroughbred gelding fed on a normal maintenance ration and given light exercise received 3 injections of 174, 100 and 108 mg. T 1824 with intervals of 102 and 210 min.; 19 samples of blood were taken in just over 10 hr. for estimation of the rate of disappearance of the dye.

The horse weighed 496 kg.; the plasma volume was estimated as 5.237 per cent. of this and the total blood volume by calculation as 8.114 per cent.—W. A. Greig.

606

MARINONI, U. and VOLTA, A. Il volume del sangue e del plasma, determinato col metodo

delle emazie segnate con P^{32} , nella poliglobulia sperimentale da cobalto. [The blood and plasma volume, estimated with red cells labelled with ^{32}P , in experimental cobalt polycythaemia.] *Arch. Sci. biol., Bologna*, 1954, 38, 197-205. [Ist. Patol. Med., Univ. Milan.]

In 12 rabbits treated with cobalt chloride, 5 or 10 mg. per kg. bodyweight daily for 35 to 40 days, the red cell count rose from 4 or 5 million per c.mm. to 7 or 7.5 million. Red cells labelled with ^{32}P were used to estimate blood volume after 20 days and at the end of treatment and again 20 to 25 days later.

Total blood volume increased in each animal during cobalt treatment, red cell volume increased in all and plasma volume in all except one; the changes were reversed when treatment ceased. Cobalt thus induced true polycythaemia.

RAFSTED, S. and SWAHN, B. Studies on lipids, proteins and lipoproteins in serum from newborn infants. *Acta paediat.*, 1954, 43, 221-234. [Paediat. Clin., Univ. Lund.] French, German and Spanish summaries.

A sample of cord blood was obtained at birth and a sample of capillary blood at 1 to 6 days of age from 50 healthy full-term infants. Mother's milk was the sole food of the infants studied. Total and free cholesterol, phospholipins and total lipids were estimated by micro-methods and protein and lipid fractions in 0.6 ml. serum were separated by electrophoresis. Mean values and ranges are tabulated. Cholesterol, total lipids and phospholipins increased greatly during the first few days of life. All the lipid fractions increased, the greatest increase being in the β -fraction. Of the protein fractions α - and β -globulins increased and γ -globulin decreased; albumin showed little change. These changes are shown graphically.

TÖRNBLOM, N. Venoarterial lipid, protein and polysaccharide differences. *Acta med. scand.*, 1954, 149, 369-376. [Med. Clin., Univ. Hosp., Upsala.]

Previous work is discussed which reports higher lipid levels in serum, plasma and blood from veins than in that from arteries. It is concluded that the apparent difference for whole blood cannot be real.

However, total proteins and polysaccharides were higher in venous than in arterial plasma, the difference being of the same relative magnitude as that in plasma lipid content, and the levels in CO_2 -treated arterial plasma resembled those in venous plasma. It is considered that the differences in plasma protein and polysaccharide values

can be explained by the Hamburger phenomenon, i.e., the increase in red cell volume when blood takes up CO_2 , caused by passage of water and Cl ions into the red cells, and the opinion is expressed that the difference in plasma lipid values is produced in the same way.

The method of Bloor (*J. Biol. Chem.*, 1914, 17, 377) is shown to give incomplete extraction of serum lipids.—D. Duncan.

609

HOMOLKA, J. Die Bluteiweisskörper und ihre Veränderungen in der elektrophoretisch-polarographischen Forschung. [Blood proteins and their changes in electrophoretic-polarographic studies.] *Ann. paediat.*, 1954, 183, 96-118. [I. Kinderklin., Univ. Prague.] English and French summaries.

A simple method for micro-electrophoresis on filter paper is described. After the paper is dried at $37^\circ C$. strips are immersed in a 0.9 per cent. NaCl solution. The proteins redissolve, Brdicka's Co^{++} solution is added and the polarographic analysis of the test tubes is made, with constant and reproducible results.

The average values for 12 normal samples of serum were: albumin 51.3 and α -, β - and γ -globulins 13.7, 22.6 and 12.4 per cent. By applying Brdicka's denaturation process to the electrophoretically separated proteins it is shown that only the albumins, and not the globulins, are subject to alkaline denaturation. The polarographic changes in the globulins are explained by the variations in their solubility with and without alkali. The different character of the proteins in health and disease is demonstrated graphically and numerically. The material on which this work was based consisted of 130 polarograms obtained from the sera of 75 patients.—M. B. Richards.

610

HOCH, H. and CHANUTIN, A. An electrophoretic study of human plasma stored at room temperature. *J. Biol. Chem.*, 1954, 209, 661-669. [Dept. Biochem., Sch. Med., Univ. Virginia, Charlottesville.]

Within 36 hr. of storage at room temperature of serum and plasma, electrophoretic patterns showed that a portion of the β -globulin, which varied from 25 to 50 per cent. of the total, had increased in mobility and appeared as a new peak between α_2 -globulin and the remaining β -globulin. After more than 1 month of storage 4 plasma samples had a component lying between α_1 - and α_2 -globulin, apparently the "labile" β -globulin which had increased in mobility. Two other plasma samples had a mobility of "labile" β -globulin similar to that of α_2 -globulin, and α_2 -globulin increased in concentration for at least 2 months. After 1 to 3

N.A. and R., January 1955

months the mobilities of γ -globulin and fibrinogen increased until at 6 or 7 months fibrinogen no longer had a separate peak.

The plasma patterns obtained were much changed after 10 months' storage in the presence of glucose and at 77 months only 2 main components were seen. Storage with sodium citrate alone, even for 8 years, preserved the original pattern.

MUKHERJEE, K. L. and WERNER, G. **Enzyme activity and protein concentration in the serum of patients with malnutrition.** *J. Lab. Clin. Med.*, 1954, **43**, 727-731. [Sch. Trop. Med., Calcutta.]

α -Amylase, lipase, total protein and albumin were estimated in 28 samples of blood serum from 15 patients [age not stated] with nutritional oedema. The amylase activity ranged from 33 to 261 Smith Roe units. There was a linear relation to albumin only when that was below 2.5 g. per 100 ml. serum; otherwise the amylase content was normal. The correlation of amylase with total protein content was not statistically significant. Lipase activity in Willstaetter units was related neither to albumin nor to total protein content.

The findings are compared with those of other workers on children with kwashiorkor (see Absts. 1754, 2194, Vol. 23). A shortage of precursor proteins is suggested as limiting the formation of serum amylase.—D. Harvey.

WATKIN, D. M., LAWRY, E. Y., MANN, G. V. and HALPERIN, M. **A study of serum beta lipoprotein and total cholesterol variability and its relation to age and serum level in adult human subjects.** *J. Clin. Invest.*, 1954, **33**, 874-883. [Sect. Gerontol., Nat. Heart Inst., Nat. Inst. Health, Bethesda, Md.]

Serum cholesterol and some classes of β -lipoproteins were estimated at intervals for several weeks in blood samples obtained from 68 adult and elderly men. The subjects were nearly all housed in an institution for reasons of poverty and none was studied in this investigation if he was known to be suffering from any disease.

The results showed no positive correlation between total cholesterol values and the values of

any or all of the classes of lipoproteins which were measured. No significant difference in variability for total cholesterol and lipoproteins was found among several age groups.—G. A. Garton.

614

LEINWAND, I. and MOORE, D. H. **Serum lipid and protein fractions. 9. Comparison of ninety-six patients with vascular disease and sixty normal controls (with additional notes on blood donors).** *Circulation*, 1954, **10**, 94-100. Spanish summary.

In the presentation of results patients were grouped according to their disease and for each group and for the controls mean values and standard deviations of albumin and globulin fractions in serum were tabulated. These showed a general increase in β -globulin in all the disease groups. In *arteriosclerosis obliterans* the increase in β -globulin was related to the occurrence of high serum lipid levels, but only about half of the patients in this group had abnormal serum lipid levels. All disease groups showed lower mean values for albumin. The lowest albumin and the highest β -globulin values were in the group of patients with primary, essential xanthomatosis. Among controls professional blood donors had a lower albumin and a higher globulin value than non-professional donors.—F. C. Aitken.

615

ROSENBERG, I. N., YOUNG, E. and PROGER, S. **Serum lipoproteins of normal and atherosclerotic persons studied by paper electrophoresis.** *Amer. J. Med.*, 1954, **16**, 818-821. [Ziskind Res. Labs., New England Centre Hosp., Boston, Mass.]

Serum samples were from a group of 18 women of whom 10 were healthy and 8 were in hospital but had no cardiovascular sign, and from a group of 21 patients, 16 men and 5 women, judged to have coronary atherosclerosis. The sera were examined by the method given in Title 1800, Vol. 23.

Electrophoretograms for lipids showed 2 zones for which the dividing line corresponded approximately with the β -globulin band for proteins. In normal subjects 81.6 per cent. of the total area was in zone 1 and 18.4 per cent. in zone 2; in the patients, 70.3 and 29.7 per cent. There was overlapping of the groups, which limited the value of the electrophoretogram as a test for atherosclerosis; it may be of more use for the estimation of the relative amounts of β - and α -lipoprotein in serum.

D. Harvey.

616

COLLENS, W. S., BANOWITCH, M. M. and COLSKY, T. **Lipoprotein studies in diabetics with arteriosclerotic disease.** *J. Amer. Med. Assoc.*,

1954, 155, 814-817. [Diabetic Res. Lab., Maimonides Hosp., Brooklyn, N.Y.]

Values for S_r 12-20 and S_r 20-100 lipoproteins in the blood of 34 men and 19 women with diabetes and advanced arteriosclerotic disease did not differ from Gofman's values for normal persons (Abst. 686, Vol. 20). Of 32 who had also diabetic renal disease (Kimmelstiel Wilson syndrome), 23 had an atherogenic index (Abst. 5143, Vol. 24) above normal, against only 7 of the other 21. The proportion with raised atherogenic index was even higher in those with coronary artery disease in addition, but not in those with coronary artery disease but without diabetic renal disease.

S_r 12-20 lipoproteins in the same patient at different times might vary by over 30 per cent. Gofman's finding that lipoproteins tend to be high in those with high serum cholesterol was confirmed.

In the discussion the view is expressed that "the significance of the concentration of the serum lipoproteins . . . needs to be further evaluated . . . the reason may lie in the fact that no satisfactory figure for the true normal has been established".

[Some of the tables are given only in authors' reprints.]—W. M. Deans.

617

HORLICK, L. Serum lipoprotein stability in atherosclerosis. *Circulation*, 1954, 10, 30-42. [Dept. Med., McGill Univ., Montreal.] Spanish summary.

The lecithinase turbidity test was applied to the sera of 50 patients with coronary disease, mean age 57.7 years, 131 young controls, mean age 22.1 years, and 50 older controls, mean age 50.2 years. Lipids were estimated in all sera. The degree of final turbidity was related to serum lipid levels. There was a higher percentage of high final turbidity values in the group with coronary disease. Onset of turbidity was early in a higher proportion of the group with coronary disease; this was attributed to relative instability of lipoproteins in these subjects.—F. C. Aitken.

OFF, K. Umsatz von radioaktiven Serum-eiweissfraktionen. 3. Versuche an normalen Kaninchen. [Turnover of radio-active serum protein fractions. 3. Experiments on normal rabbits.] *Ztschr. ges. exp. Med.*, 1954, 123, 434-441. [Med. Klin., Freie Univ., Berlin.] For parts 1 and 2 see Abst. 4627, Vol. 24.

The turnover of blood protein fractions in normal rabbits was studied by means of ^{131}I -labelled serum. In all fractions the fall in activity took place in 2 phases, a relatively quick fall followed by a regular, slow decline. Mixing of intra- and extra-vascular protein took place more quickly with albumin and γ -globulin than with β - and α -globulin. The distribution space of α - and β -globulin was greater than that of the albumin and γ -globulin. The turnover was quickest for α_2 -globulin, followed by α_1 -, β - and γ -globulins, and finally albumin. The amount of protein renewed daily amounted to 1/7 of the albumin and about 1/4 of the globulins in the body.

KRÜSKEMPER, H. L. and SCHULZE, G. Stoffwechseluntersuchungen bei langdauernder Cholesterinfütterung am Kaninchen. 1. Über das Verhalten von Eiweissfraktionen, Lipiden und Fermenten im Serum. [Metabolism studies with rabbits given cholesterol for a long time. 1. Behaviour of protein fractions, lipids and enzymes in serum.] *Arch. exp. Pathol. Pharmacol.*, 1954, 222, 562-574. [Med. Klin., Univ. Göttingen.]

Administration of cholesterol to 13 rabbits for 26 to 89 days caused a mean increase of 23 per cent. in total serum protein. This was due mainly to a rise of about 370 per cent. in β -globulin and a smaller rise in γ -globulin; serum albumin fell by about 18 per cent. The changes were apparent after 6 weeks, and showed no tendency to increase or go back with more prolonged feeding. The total lipid content of the serum increased, with an increase in all the fractions studied. Blood cholesterol increased sixfold from the normal value of 120.1 mg. per cent.; from the sixth week the values ranged between 350 and 1280. The cholesterol: phosphatide ratio increased, as did the neutral fats and "unknown substances". Cholesterol estimations made on serum gave higher values than those made on an alcohol-ether extract, the differences being significantly correlated with the β -globulin content of the serum. Serum lipase increased significantly in activity; acid and alkaline phosphatase showed no measurable change. Cholinesterase activity remained unchanged for 10 weeks, then increased.

It is suggested that the findings are probably the expression of a deep-seated disturbance of fat metabolism, combined with physico-chemical changes in the structure of the serum-protein-lipid complex.—M. B. Richards.

CHOPARD, P. Bestimmung der Eiweissfraktionen des Blutserums bei den Haustieren mit der Papierelektrophorese, unter Berücksichtigung verschiedener Faktoren. [Estimation of protein fractions in the blood serum of farm animals by electrophoresis on paper, with consideration of several modifying circumstances.] *Ztschr. Tierzücht. Züchtungsbiol.*, 1954, **63**, 21-52. [Inst. Tierzücht. Hyg., Univ. Berne.] French summary.

The history of techniques for estimating blood proteins and of electrophoretic separation in particular is briefly reviewed. For the present study blood was taken from the jugular vein of horses, cattle and goats, and during bleeding at slaughter of pigs, sheep and fowls. Rabbit blood was taken from the ear vein. Serum was separated in the centrifuge from clotted blood, except horse blood, which required no spinning. Total protein was estimated with a Zeiss immersion refractometer: separate proteins by the technique of Grassmann and Hannig (Abst. 1240, Vol. 23).

The results are reported in detail for 9 stallions, 8 mares and 4 geldings, 20 pigs, 22 white hill sheep, 14 Saanen goats, 16 Leghorn hens, 6 dogs and 4 cats. A special study was made of 1 adult and 4 young rabbits in Berne and at the high alpine station on the Jungfrauoch. In the young, β - and γ -globulins increased at high altitude; in the mature rabbit the globulins decreased and albumin increased.

Mean values are given for 11 Simmenthal cows. In an experiment on 5, there was an apparent increase in total protein after feeding which, with the method used, might be caused by either fat or sugar in blood and was not confirmed by Kjeldahl estimation. Milking had no significant effect on the same 5 cows. They were studied also during the transition from hay to grass. Four showed a significant increase in total protein and all a significant reduction of albumin 4 days after the transition to grass alone. On mountain pasture there was no change in total protein or its fractions.

For 3 calves at birth and soon after, values were low and rose steeply. In 7 out of 19 preparations no γ -globulin was found; α -globulin fell in the first few days and the rise was accounted for by albumin.

Mean normal values are summarised as follows, total protein in g. per 100 g. serum and fractions as percent. of total in the order albumin, α -, β - and γ -globulin:

Horse	. 7-00	40-9	18-5	19-1	21-5
Pig .	. —	39-2	21-9	15-6	23-3

WEHMEYER, P. Concentration of plasma proteins in the ox. 1. Individual differences. *Nord. Vet.-Med.*, 1954, **6**, 717-736. [Statens Seruminst., Copenhagen.] German and Danish summaries.

Blood samples from 206 cattle showed that breed, sex and age did not influence serum protein values, which were also independent of cell volume and sedimentation rate. In one group a high serum protein value was accompanied by a high γ -globulin value, but in another there was no relation between albumin and globulin values. Globulin was slightly higher and albumin slightly lower in the oldest cows.

The logarithm of the formol-gelatination time was roughly proportional to both γ -globulin and globulin value. Fibrinogen value was not related to globulin value.—A. Hepburn.

624

WEHMEYER, P. Variation in the composition of the blood in cows during thirst, after intake of water, and on hunger. *Acta pathol. microbiol. scand.*, 1954, **34**, 518-520. [Statens Seruminst., Copenhagen.]

Five healthy cows and 5 culled cows were fed on hay and deprived of water for 2 days. In all there were increased serum albumin and protein concentrations. Cell volume increased only in the healthy cows.

Water was supplied and after 30 min. or 2 hr. serum albumin fell markedly, serum protein and cell volume less. Globulin concentration rose in the healthy cows.

The blood composition returned to normal in the 5 culled cows after grazing for 3 days. When water alone was supplied for 2 days no significant difference was seen in plasma protein concentrations or cell volume.—A. Hepburn.

625

HEIM, W. G. and SCHECHTMAN, A. M. Electrophoretic analysis of the serum of the chicken during development. *J. Biol. Chem.*, 1954, **209**, 241-247. [Dept. Zool., Univ. California, Los Angeles.]

Serum was obtained from chicken embryos of 10 to 21 days incubation age, from chickens up to

3 months old and from adult cocks and laying hens. The average mobilities of the component proteins and the percentage composition are presented in tables and diagrams.

Pre-albumin components, probably not identical, occurred in sera from embryos and laying hens, but not in males or immature females. Albumin represented about 30 per cent. of the total protein at all stages. α -Globulin decreased and β -globulin increased during embryonic life and γ -globulin increased for some days before and after hatching.

MÜTTER, D. and WORTMANN, V. Zum Aminosäureaufbau der Serum- und Gewebeeisweißkörper gesunder Menschen und Tiere. [Amino-acid composition of serum and tissue proteins of healthy men and animals.] *Biochem. Ztschr.*, 1954, 325, 448-458. [Forschungsinstitut, Diabetes, Karlsburg, Krs. Greifswald.]

Nineteen amino-acids were estimated quantitatively by chemical methods or by paper chromatography in the electrophoretically separated serum proteins of man, and also in the proteins of organs of man, pig, dog, rabbit and rat. The results for human serum agreed well with those of other authors, except that the methionine content of albumin, 3.1 per cent., differed from that given by some others, 1.3 per cent. Serum albumin had a considerably higher content of cystine, methionine, arginine, glutamic acid and phenylalanine than γ -globulin, but the latter was richer in tyrosine, tryptophan, glycine, serine and threonine; α - and β -globulin, when compared with other proteins, also had a characteristic amino-acid composition.

In man the composition of tissues closely resembled that of the serum proteins both qualitatively and quantitatively, except for the presence of hydroxyproline in a few organs: pancreas, heart, skeletal muscle and thyroid. Lung, pancreas and skeletal muscle contained nearly twice as much arginine as the other tissues. The thyroid was rich in cystine, the liver in methionine and threonine, and the pancreas in glycine. Human and animal tissue proteins also differed little in their amino-acid composition. In the pig, as in man, liver and heart were rich in methionine. In the dog the highest cystine values were found in the brain and the pituitary. The dog differed from man in that hydroxyproline was found in all organs except the liver, and almost always also in the urine. The adrenals of dog and rat contained about twice as much arginine as most of the other tissues. There was no reason to suspect the presence of unknown amino-acids.—M. B. Richards.

JIMÉNEZ DÍAZ, C., AGUIRRE, M. and ARJONA, E. La glucosamina del plasma y sus modifica-

ciones patológicas. [Plasma glucosamine and its pathological modifications.] *Rev. clín. española*, 1954, 52, 374-381. [Inst. Invest. Med., Madrid.] English, German and French summaries.

For 10 normal subjects plasma glucosamine ranged from 75 to 124 mg. per 100 ml. In diseases with increased destruction of tissues (infections and neoplasms) there were higher levels of plasma glucosamine, and also in collagen diseases, especially rheumatic disease, rheumatoid arthritis and chronic infectious asthma. For 52 patients with clinically active cardio-articular rheumatism values ranged from 153 to 445 mg. per 100 ml., and in 54 patients with rheumatoid arthritis, classified according to its intensity, there was clear parallelism between the activity of the disease and the increase in plasma glucosamine. When treatment with salicylate, ACTH, cortisone or N mustards was effective, as it usually was, there was a fall in serum glucosamine. The estimation of glucosamine is of great clinical importance as a guide in the treatment of cardio-articular rheumatism with these drugs.—M. B. Richards.

MUNKVAD, I. and VESTERDAL, J. Plasma glutamine and glutamic acid in children with brain diseases as compared with normal children. *Acta paediat.* 1954, 43, 320-326. [Univ. Clin. Paediat., Rigshosp., Copenhagen.] French, German and Spanish summaries.

Glutamine and glutamic acid were estimated by the method of Krebs (Abst. 3940, Vol. 18) in the plasma of 25 children with brain disorders and 12 without. Glutamine was significantly lower in the blood of those with brain disorder; in glutamic acid there was no difference, and both varied so greatly in the same individual at different times that the method is of no diagnostic value.

SENAPATI, J. M., SUBRAHMANYAM, K. and BANERJI, S. M. Plasma cholesterol and its fractions in apparently healthy individuals. *J. Indian Med. Assoc.*, 1954, 23, 386-387. [Dept. Physiol., Sriram Chandra Bhandj Med. Coll., Cuttack.]

In 30 Indian males, aged 20 to 30 years, mean plasma total cholesterol was 171.8 mg. per cent., range 155.2 to 190.2, mean free cholesterol 54.03 mg. per cent., range 47.1 to 65.2, and mean (calculated) esterified cholesterol 117.8 mg. per cent., range 99.0 to 143.0.—J. S. Thomson.

632

GORECZYK, L. Über den Fettsäuregehalt des Depotblutes der Milz. [Fatty acid content of stored blood in the spleen.] *Biochem. Ztschr.*, 1954, **325**, 477-481. [Krankenhaus Staatsbahnen, Budapest 6.]

Stored blood from the spleen of dogs gave a fatty acid content ranging from 234 to 454 mg. per cent. for 7 samples, with a mean value of 385. In peripheral blood from the femoral vein the fatty acid content ranged from 195 to 334, with a mean value of 296 mg. per cent. The average difference in fatty acid content between stored blood and peripheral blood was 29 per cent. After circulating blood was allowed to flow through the spleen the spleen serum gave the same fatty acid content as peripheral serum. This increase in the fatty acid content of the stored blood probably plays a part in the esterification of cholesterol in the spleen.—M. B. Richards.

633

VAN SOEST, P. J. and BLOSSER, T. H. A detailed study of levels of certain blood constituents in normally calving dairy cows and in dairy cows with parturient paresis. *J. Dairy Sci.*, 1954, **37**, 185-194. [Dept. Dairy Sci., State Coll. Washington, Pullman.]

Blood glucose and pyruvic acid, serum Ca, plasma P and haematocrit were estimated before and after parturition in 4 normal cows and 4 cows, one at 2 parturitions, which had a history of milk fever.

In all parturient cows blood glucose and pyruvate rose and 3 cows showed increases with the development of milk fever. Pyruvate was higher during milk fever than at parturition. Plasma P and serum Ca declined erratically in the cows with signs of milk fever, but only slightly in normal cows. The haematocrit increased at parturition in all, and gradually declined to a minimum, generally 15 to 30 days *post partum*.

For 48 hr. after parturition there was a positive correlation between glucose and pyruvate in all and a negative correlation between plasma P and both blood glucose and pyruvate in the cows with milk fever.—A. Hepburn.

STRENGERS, T., MAAS, J. W., ROTTINGHUIS, H. and FEHMERS, G. A. Plasma electrolytes in the neonatal period. *Acta paediat.*, 1954, Vol. 25, No. 1

43, 342-346. [Clin. Chem. Lab., Onze Lieve Vrouwe Gasthuis, Amsterdam.] French, German and Spanish summaries.

Data are presented for Na, K, Cl and CO₂ in samples of blood plasma from 30 premature and 32 full-term infants and from 25 adults. Those for the infants are for 1, 2, 3, 5 and 7 days of age, but samples were not obtained from all on each of these days. In both groups of infants there was, on the first day, slight acidosis attributable to anaerobic metabolism *in utero* or during birth. In the full-term infants it disappeared rapidly and adult levels were reached by the 7th day. In the premature group the acidosis persisted, largely because of continuing high levels of Cl which, in turn, are thought to be related to incomplete development of the kidneys.—D. Harvey.

GUNDERSEN, K., BRADLEY, R. F. and MARBLE, A. Serum phosphorus and potassium levels after intravenous administration of glucose. Their use as diagnostic acids in diabetic and non-diabetic subjects with and without liver disease. *New Engl. J. Med.*, 1954, **250**, 547-554. [Baker Clin. Res. Lab., New England Deaconess Hosp., Boston, Mass.]

Eleven normal subjects and 41 patients, in all 38 men and 14 women, were given intravenous glucose tolerance tests. Glucose tolerance was considered normal when the fasting level was 100 mg. per 100 ml. or less and this was regained within 120 min. after glucose infusion. These criteria were met by 24 subjects and were not met by 24, and 4 were borderline.

Serum P fell in normal subjects by from 4 to 35 per cent., average 19 per cent., and in diabetics by 5 to 32, average 18 per cent. Serum K showed slight variations in either direction, without significant difference between groups.

Liver function was judged to be normal in 26 subjects, of whom 7 were diabetic and 2 borderline; liver disease was unquestioned in 5, of whom 4 were diabetic; the other 21 had only suggestive evidence of impaired liver function. The changes in serum P or K could not be used diagnostically. D. Duncan.

GRAD, B. Diurnal, age, and sex changes in the sodium and potassium concentration of human saliva. *J. Gerontol.*, 1954, 9, 276-286. [Gerontol. Unit, Allan Mem. Inst. Psychiat., McGill Univ., Montreal.]

The Na and K content of mixed, unstimulated saliva from 52 males and 58 females aged from 5 to 99 years was estimated by direct intensity flame photometry. Samples of 4 ml. were taken from each subject before each meal and on retiring at night. The mean content of all the samples from 101 subjects who provided all 4 specimens was 11.62 ± 0.42 m. equiv. Na and 24.98 ± 0.46 m. equiv. K per litre; the mean Na:K ratio was 0.46 ± 0.02 . A diurnal variation occurred, mostly in Na content; the highest values for Na:K occurred before breakfast and the lowest values before lunch or before supper with a tendency to rise before retiring at night. The Na content of saliva from men aged from 40 to 92 years was significantly higher than that of men under 40; no significant difference occurred among women in 2 similar age groups. The K content of saliva was significantly higher in both men and women aged 40 or over than in subjects of the same sex younger than 40. There was no significant difference in the salivary Na:K ratio between subjects over and those under 40. Men aged 40 and over had significantly higher salivary Na contents and Na:K ratios than had women over 40; there was no such difference due to sex in the younger subjects or in the salivary K content between sexes at any age.

Since it is known that the salivary Na:K ratio is inversely proportional to the degree of activation of the adrenal cortex, it is suggested that women in later life have a higher level of adrenal cortical function than men of the same age.

TISSUES

643

KRAYBILL, H. F., HANKINS, O. G. and FARNWORTH, V. M. Adaptation of anthropometric and roentgenological measurements for appraisal of the percentage of bone in cattle. *J. Appl. Physiol.*, 1954, 7, 13-18. [Animal and Poultry Husb. Res. Branch, Agric. Res. Serv., U.S. Dept. Agric., Beltsville, Md.]

Measurements were made before and after slaughter on 75 cattle of different breeds and conformation, from 136 to 1870 lb. in weight and from 52 to 4543 days in age. Lateral X-ray photographs were made of the lower leg area, the large metacarpal (cannon) bone and its surrounding tissues, with a standardised technique. The width and lateral area of the bone and the lateral area of the soft tissue were estimated from the X-ray photographs, and the density of the bone was estimated hydrostatically after death. Measurements were made of the bone, and the circumference of the leg was also measured in life. The bone content of the whole animal was calculated from analysis of ribs.

Correlations between all the measurements are presented. It is concluded that for practical purposes the density, width of bone and circumference of the metacarpal bone were the most significant indicators of the total bone content of the body. The regression equation form these 3 variables is:

Percentage of bone = $83.12 - 1.24(\text{Width of bone}) - 33.84(\text{Density of bone}) - 0.28(\text{Circumference of bone})$.

The estimated standard error is ± 3.79 . Density was the most significant factor, and although less accurate than the triple measurement it appeared to be useful for practical purposes.—D. Duncan.

WALSER, M. and BODENLOS, L. J. Composition of skin as compared with muscle. *Amer. J. Physiol.*, 1954, 178, 91-96. [Naval Med. Res. Inst., Bethesda, Md.]

Half-inch strips of skin from round the trunk of 13 normal female rats were extracted with ether

N.A. and R., January 1955

and in the residue Cl was estimated with thio-cyanate and Na and K by flame photometer. The results are tabulated along with values for Na, K and Cl in the serum of the same rats and values for sodium space, chloride space and non-extracellular chloride of skin calculated therefrom.

Na, Cl and water contents were almost constant; these and K were lower than in dog skin (Abst. 3165, Vol. 13) or human skin (Abst. 459, Vol. 15).

Fat, water, collagen by the method of Lowry *et al.* (Title 817, Vol. 11) and K were estimated in skin from other rats and in muscle from 3 of these. Non-collagen solids were calculated by difference. Relative to these, the K content of skin was much less variable than when expressed in terms of fat-free dry tissue; it ranged from 35.5 to 54.8 mM per 100 g. fat-free non-collagenous dry tissue, mean 47.4 [given as 42 in Table 4, p. 95]. The corresponding mean value for muscle was 38.4, and for the whole body, from analyses of 3 carcasses and on the assumption that collagen forms 5 per cent. of the body by weight, 36. It is suggested that fat-free non-collagenous dry tissue is proportional to the mass of parenchymal cells and that intracellular constituents should be related to it. The distribution of body chloride also is discussed in the light of the findings.

HRACHOVEC, J. Sur la variation de composition du muscle et du foie au cours du développement du lapin. [Variation in the composition of muscle and liver during development in the rabbit.] *C.R. Acad. Sci.*, 1954, 239, 306-308.

Liver and hindlimb muscle from rabbits of different ages from the 21st day of foetal life to adults were analysed.

The hindlimb muscles formed an increasing percentage of the bodyweight, from 1.8 in the embryo to 7.5 in the adult, but the liver reached its maximum relative weight of 9.5 to 10 per cent. about the 24th day of foetal life and thereafter declined until it represented 2.1 to 2.3 per cent. of the adult bodyweight.

The contents of lipid P and of free cholesterol, expressed in mg. per 100 g. fresh tissue, increased in both tissues until about one or two weeks after birth; their levels then fell in muscle but continued to rise in the liver so that in the adult the values for liver were 5 times as high as those for muscle. However, the ratios of lipid P : deoxyribonucleic acid and free cholesterol : deoxyribonucleic acid rose in both tissues in a similar way. The fall in lipid constituents in muscle is due mainly to the increase in protein content.

HRŮŽA, Z. Ztráty hmoty některých parenchymatousích orgánů hladověním v průběhu onto-

Vol. 25, No. 1

genesis. [The loss of substance in some parenchymatous organs due to fasting during growth.] *Čsl. fysiolog.*, 1954, 3, 235-242. [Res. Inst. Human Nutrit., Prague.]

Rats were fasted until they lost 30 per cent. of their initial bodyweight. The greatest loss of bodyweight was observed in rats 38 days old. With newborn rats the loss of substance of the brain, liver, stomach and kidney was proportional to the loss of the whole body. In rats some days after birth the loss of substance of brain and kidneys was slower and that of liver and stomach faster than the loss of other tissues. During development the water content of most organs, except the stomach, decreases. The water content of the organs is increased by fasting, especially in early life.—M. Prokšová (Czechoslovakia).

FRANÇOIS, J., RABAËY, M., WIEME, R. J. and NEETENS, A. Étude des protéines cristalliniennes hydrosolubles par l'électrophorèse dans la cataracte expérimentale. [Electrophoretic study of water-soluble lens proteins in experimental cataract.] *Ann. Oculist.*, 1954, 187, 593-610. [Clin. Ophthalmol., Univ. Ghent.] English summary.

The changes in the lens proteins of rats at different stages of galactose-induced cataract were studied by paper electrophoresis. The tables and electrophoretograms show that the cataract lens is about 50 per cent. heavier than the normal lens of a rat of the same weight. In the normal lens the mean percentage of water-soluble proteins is 64, in lenses with slight opacity it is 46, and in those with marked opacity 30.6. This diminution takes place at the expense of all fractions, so that the relative concentration of the different fractions in the cataract lens is nearly the same as in the normal lens. In nuclear cataract, where the lens nucleus is much more opaque than the cortex, the diminution of fraction III is proportionately greater, since this fraction is relatively higher in the nucleus than in the cortex. In the electrophoretograms of cataract lenses the curves tend to become flattened, and when the cataract is complete there is a more or less homogeneous zone in which it is difficult to distinguish separate fractions.—M. B. Richards.

NOBLE, N. L., BOUCEK, R. J. and LEWIS, G. T. A relationship of tissue lipids to sex and body weight in the albino rat. *Circulation Res.*, 2, 1953, 311-314. [Miami Heart Inst., Fla.] Male and virgin female rats weighing from 40 to 625 g. and fed on stock diet were used, 27 rats in all.

There was no significant difference in the mean

phospholipin, total or residual (total minus phospholipin) fatty acid contents in the liver or phospholipin in the heart between females and males of the same weight, but when 5 large males weighing 400 to 625 were included the females had a significantly greater concentration of total liver fatty acids. The concentrations of liver phospholipin in the male, heart phospholipin in the older male and in the female, and total liver fatty acids in the young male decreased significantly with increase in bodyweight.

Female rats and older males had more ketone bodies in urine and liver than the younger males, and females had more in the heart than males.

654

FORBES, R. M., COOPER, A. R. and MITCHELL, H. H. On the occurrence of beryllium, boron, cobalt, and mercury in human tissues. *J. Biol. Chem.*, 1954, 209, 857-865. [Div. Animal Nutrit., Univ. Illinois, Urbana.]

The concentration of Be, B, Co and Hg were estimated in tissues from a normal man. Be was present in lung, kidney and liver in concentrations of 0.002 to 0.0004 p.p.m. fresh tissue, but was absent from skeletal muscle. The skeleton contained most Be, 0.90 p.p.m., and next came the kidneys, 0.248 p.p.m. Liver and skin contained 0.056 and 0.050 p.p.m. Co. Most Hg was found in the nervous system, 0.047, and in the heart, 0.052 p.p.m. All tissues analysed contained B, Co and Hg.—A. Hepburn.

655

OLSON, K. B., HEGGEN, G., EDWARDS, C. F. and GORHAM, L. W. Trace element content of cancerous and noncancerous human liver tissue. *Science*, 1954, 119, 772-773. [Dept. Med., Subdiv. Oncol., Albany Med. Coll., N.Y.]

Liver tissue from 6 patients who had died from cancer of the gastrointestinal tract, of whom 4 had liver metastases and the other 2 portal cirrhosis, 1 child dead from acute lymphatic leukaemia with hepatic infiltration, and 6 dead from diseases other than cancer were analysed for trace elements by a method already described (Abst. 87, Vol. 24).

In agreement with other studies, Zn was low in cancerous tissue, mean 18 p.p.m., compared with non-cancerous liver, mean 38 p.p.m. or the unaffected portions of liver with metastases, mean 80 p.p.m. Cu was very high in liver from the patients who had portal cirrhosis but not liver metastases. Fe, Zn, Cr and Co were high in liver from the patient with leukaemia.—W. M. Deans.

656

MCLENDON, J. F. and FOSTER, W. C. Protein bound iodine in extra thyroidal human tissues. *Arch. internat. Pharmacodyn.*, 1953-54, 96, 287-290. [J. Gershon-Cohen Found., Albert Einstein Med. Centre, Northern Div., Philadelphia, Pa.]

Samples of tissue from 40 subjects postmortem were analysed for protein-bound iodine. The tissue was frozen in liquid nitrogen, pulverised and

N.A. and R., January 1955

extracted with methanol. The methanol was decanted off the precipitated protein and replaced by acetone. This protein suspension was poured into 12 cm. of 3/8 in. cellophane tubing stoppered with a piece of grapevine. The acetone escaped through the grapevine while the protein was collected in the cellophane tube and dried. It was then burnt in a platinum tube in oxygen and analysed for I by the method of McClendon and Bratton (Abst. 1505, Vol. 8). The average value for the protein-bound I content of skeletal muscle was 5.85 μ g. per 100 g. tissue, for heart muscle 6.095, for liver 8.425 and for kidney 8.0.

659

WEITZEL, G., STRECKER, F. J., ROESTER, U., BUDDECKE, E. and FRETZDORFF, A.M. Zink im Tapetum lucidum. [Zinc in the tapetum lucidum.] *Hoppe-Seyler's Ztschr.*, 1954, 296, 19-30. [Biochem. Abt., Med. Forschungsanst., Max-Planck-Gesellsch., Göttingen.]

It had already been reported (Title 861, Vol. 24) that the zinc content of the several parts of the eye, with the exception of the choroid, was not high, but that the choroid had a very high zinc content. It is now shown that this is true of carnivores, but not of ruminants, and that, in contrast to the findings of Bowness *et al.* (Title 548, Vol. 23), albino rabbits have just as much Zn in the choroid as pigmented rabbits.

The choroid was further dissected and the Zn

Vol. 25, No. 1

was found to be concentrated in the iridescent layer (*tapetum lucidum*) with values up to 8.5 (average 7.2) per cent. of dry matter in the dog and up to 13.8 (average 11.6) per cent. in the fox. The cat had less.

Injection of 100 mg. dithizone per kg. body-weight intravenously into dogs produced a bright red colour in the tapetum followed by dissolution, separation of the retina and blindness. 8-Hydroxyquinoline had much less effect and dithizone had less effect on cats than on dogs. Those treated with dithizone had only a small fraction of the normal Zn content in the whole choroid.—I. Leitch.

MACDONALD, I. Chemical analysis of human foetal skull bones. *Biochem. J.*, 1954, 57, 437-439. [Dept. Physiol., Guy's Hosp., London.]

Ca, P, carbonate and collagen were estimated in the parietal and frontal bones of the crania of 21 foetuses aged 28 to 43 weeks. The Ca and carbonate contents increased with increasing foetal age; the mean proportional weekly increase on dry weight of bone was 0.04 per cent. for Ca and 0.05 per cent. for carbonate. No such increase occurred in P and collagen content. It is suggested that the increased hardness of the head associated with foetal maturity is due to an increase in the proportion of calcium carbonate in the skull bones.—G. F. Garton.

661

EASTOE, J. E. and EASTOE, B. The organic constituents of mammalian compact bone. *Biochem. J.*, 1954, 57, 453-459. [British Gelatine and Glue Res. Assoc., London, N.7.]

In a sample of compact bone 99 per cent. of the weight was accounted for by inorganic matter, collagen, a mucopolysaccharide-protein complex, and a protein fraction resistant to solution in hot water. Samples of the 3 fractions of organic matter were prepared for detailed analysis. No difference was found between bone collagen and collagen from other tissues. The protein fraction of the mucopolysaccharide-protein complex did not resemble collagen in amino-acid composition, but was similar to serum proteins. The protein resistant to solution in hot water was heterogeneous.—R. Hill.

TSYBAKOVA, E. T. Soderzhanie pirovinogradnoi kisloty v zdorovykh "normal'nykh" i karioznykh zubakh cheloveka. [Pyroracemic acid in healthy, "normal" and carious human teeth.] *Stomatologiya*, 1954, No. 2, 15-19. [Dept. Biochem., Stomatol. Inst., Moscow.]

Carious teeth had a pyroracemic acid content 3 to 5 times greater than healthy teeth. The so-called "normal" teeth, i.e. teeth without any obvious sign of caries, but from carious subjects, were intermediate between healthy and carious teeth in respect of their pyroracemic acid content. The average content was for healthy molars 0.25 mg., for premolars 0.19 mg., for incisors 0.23 mg. and for canines 0.22 mg. per cent.

For the purpose of this experiment teeth were considered to be healthy when there was a complete set in the mouth without a single carious tooth.

CHARLET, P. V., FRANÇOIS, A. C. and LEROY, A. M. Recherches sur la composition chimique des toisons de brebis. [Chemical composition of the fleece of sheep.] *Ann. Zootech.*, 1953, 2, No. 1, 11-32. [Lab. Zootech., Inst. Nat. Agronom., Paris.]

The chemical composition of fleeces from normal and "wet" (*mouilleux*) sheep was studied. The "wet" fleeces were not more hygroscopic, but they contained 41.6 per cent. water and normal fleeces only 27.1 per cent. Substances extractable with ether, ethanol or water were all present in greater quantities in the normal fleece. The ratio of water-soluble minerals to ether-soluble material was 0.555 in normal and 0.942 in "wet" fleeces, suggesting an increased secretion of the sweat glands in the latter sheep; this idea was supported by the greater alkalinity of the aqueous extract and also by the greater water content of the fleece. Sebaceous secretion was below normal.

FRAILE, A. Influencia de la corteza suprarrenal sobre el metabolismo de la rata en ayunas. [Effect of the adrenal cortex on the metabolism of the fasting rat.] *Rev. española Fisiol.*, 1953, 9, 267-276. [Lab. Fisiol. Animal, Barcelona.] English summary.

For 15 male rats of different ages and weights subjected to complete fast, survival was 6 to 9 days, and the average loss of weight 36 per cent. For 15 similar adrenalectomised rats survival was 4 to 7 days and the average weight loss 20 per cent. Administration of cortisone to the adrenalectomised fasting rats increased their survival time and weight loss to the averages for the normal animals, but deoxycorticosterone acetate (DOCA) and NaCl had no such effect.

The effect of fasting on the weights of heart, liver, spleen, kidney, testicles and thymus is recorded for both normal and adrenalectomised animals. In normal and cortisone-treated adrenalectomised animals fat deposits almost disappeared, but in the untreated adrenalectomised rats there was abundant perirenal and interscapular fat.

N.A. and R., January 1955

Diminution of liver fat was approximately the same for both normal and operated animals. The fact that adrenalectomized fasting animals lose less weight than normal animals is due not only to their shorter survival, but to the disturbance of fat and protein metabolism. Since neither DOCA nor NaCl prolongs their survival, death does not, as is frequently assumed, appear to be caused by changes in water or salt metabolism.

M. B. Richards.

ROSENMAN, R. H., FREED, S. C. and FRIEDMAN, M. (with SMITH, M. K.) **Effect of deoxycorticosterone acetate upon the blood pressure of rats fed varied dietary intakes of potassium and sodium.** *J. Clin. Endocrinol.*, 1954, **14**, 661-665. [Harold Brunn Inst., Mount Zion Hosp., San Francisco, Calif.]

Rats which failed to develop high blood pressure after removal of one kidney and the placing of a figure-of-eight ligature about the other were given injections of deoxycorticosterone acetate (DOCA), and diets differing in their content of Na and K. When the diet had a high Na : K ratio, DOCA failed to raise the blood pressure persistently; in fact, excess Na caused a depressor response, augmented when the K content of the diet was simultaneously decreased. An adequate intake of K, without excess Na, was essential for the development and persistence of high blood pressure after DOCA, but further increase of K intake did not appear to augment the effect. It is concluded that the K ion has a specific relation to production of high blood pressure by deoxycorticosterone.—M. B. Richards.

GROLLMAN, A. **The role of the kidney in the parathyroid control of the blood calcium as determined by studies on the nephrectomized dog.** *Endocrinology*, 1954, **55**, 166-172. [Dept. Exp. Med., Southwestern Med. Sch. Univ. Texas, Dallas.]

After removal of both kidneys dogs were maintained on an electrolyte-free carbohydrate and fat diet and given peritoneal lavage. The thyroids and parathyroids were previously removed from some of the dogs, which then received dried thyroid daily.

Vol. 25, No. 1.

After removal of thyroids and parathyroids tetany was relieved and serum Ca restored to normal by intraperitoneal injection of a "blood electrolyte" solution enriched with Ca. The high P level was not corrected. When the kidneys were removed from these dogs and lavage was stopped the serum Ca fell again and tetany recurred, showing that these changes do not depend on abnormal excretion of Ca and P.

In dogs with kidneys alone removed, injection of parathyroid raised serum Ca at first, but this effect declined by the sixth day; when peritoneal lavage was begun the capacity to react to parathyroid hormone was restored.

It was concluded that the parathyroid hormone acts directly on body Ca reserves and that this is independent of its action on the kidney.

The proportions of Ca, Mg and inorganic P in the blood and peritoneal fluid are compared, and indicate the proportions of these ions which are bound in the blood.—D. Duncan.

MCCLENDON, J. F., FOSTER, W. C. and BOSSHARDT, D. K. **Conditions of formation of the thyroid hormone outside the thyroid gland.** *Arch. internat. Pharmacodyn.*, 1953-54, **96**, 304-308. [Hahnemann Med. Coll., Philadelphia, Pa.]

A sample of pure thyroglobulin containing only 0.028 per cent. thyroxine I and 0.1 per cent. diiodotyrosine I was iodinated at the pH and ionic strength of blood plasma, coagulated by heat, washed and dried. It was then found to contain 0.33 to 0.34 per cent. thyroxine I and 1.4 to 3.2 per cent. diiodotyrosine I. In each of 8 rats 500 mg. of this material increased the B.M.R. by 80 to 90 per cent. whereas 500 mg. desiccated thyroid increased the rate by 95 and 3.5 mg. *l*-thyroxine increased it by 50 per cent.

Since casein contains twice the amount of tyrosine present in thyroglobulin, it was

considered of interest to test iodinated casein. Of 3 samples iodinated, only one had a thyroxine I content double that of thyroglobulin. The metabolic activity of this sample was twice as great as that of desiccated thyroid. When it was hydrolysed and lyophilised the composition of this product remained constant indefinitely. It dissolved instantly in water and when it was administered subcutaneously was 6 times more effective metabolically than when it was given by mouth.—B. W. Simpson.

WILKINS, L., CLAYTON, G. W. and BERTHRONG, M. Development of goiters in cretins without iodine deficiency: hypothyroidism due to apparent inability of the thyroid gland to synthesize hormone. *Pediatrics*, 1954, 13, 235-246. [Dept. Paediat., Sch. Med., Johns Hopkins Hosp., Baltimore, Md.] Spanish summary.

Case histories are given of 4 children with congenital cretinism in whom the thyroid glands were present and capable of concentrating ^{131}I . These patients lived in areas where I was not deficient and where diets were not excessively high in goitrogens. The 2 older children developed goitre. This type of hypothyroidism tended to run in families and was probably the result of an inborn defect in the ability of the thyroid to convert inorganic I to thyroid hormone. The goitre which developed was probably caused by excessive secretion of pituitary thyrotropin. Neither malignant change nor exophthalmos was seen. The importance of adequate and continuous thyroid treatment is stressed. A gland from a patient of this type showed multiple nodules, some with colloid and some with epithelial hyperplasia.

B. W. Simpson.

RUIZ MARTÍN, M., ORTIZ DE LANDÁZURI, E., DE LA FIGUERA, J., MORA, R. J., NÚÑEZ CARRIL, M. and MORATA GARCÍA, F. Aportaciones al estudio etiopatogénico y anatomoclínico en el bocio endémico. (Revisión de 100 tiroides.) [Contributions to the etiopathogenic and anatomoclinical study of endemic goitre. (Review of 100 thyroids).] *Rev. clín. española*, 1954, 53, 89-105. [Clín. Méd., Univ. Granada.] English, German and French summaries.

Different causes and types of thyroid enlargement are discussed. A histological study was made of glands obtained after death or after surgical extirpation. The findings are fully tabulated. The mean thyroid weight and vesicular size were greater in persons from the endemic goitre zone than in others. Abnormal glands tended to have greater variations in the size of nuclei.—D. Duncan.

680

ORTIZ DE LANDÁZURI, E., NÚÑEZ CARRIL, M., ESCOBAR DEL REY, F. and MORATA GARCÍA, F. Observaciones sobre el tiroides de perros precedentes de zona de endemia bociosa. [Observations on the thyroids of dogs from the endemic goitre area.] *Rev. clín. española*, 1954, 53, 24-28. [Clín. Méd., Univ. Granada.] English German and French summaries.

The thyroids of dogs from the endemic goitre area of Güejar Sierra were larger in proportion to bodyweight than those of dogs from the goitre-free city of Granada. Histological examination revealed small, pyknotic nuclei and enlarged vesicles in the former. The size of vesicles was more variable in the goitre zone and the curve of distribution on the basis of diameter might serve as an indication of the activity of the gland.

MAQSOOD, M. Influence of the thyroid on body temperature of rabbits and rams. *Vet. Rec.*, 1954, 66, 306-309. [Animal Res. Stat., Univ. Cambridge.]

In rabbits iodinated casein mixed with the food in small quantities did not affect the body temperature, but at or above 0.064 per cent. of the ration the temperature rose significantly, especially in summer. In Suffolk rams moderate doses of thyroprotein did not affect body temperature.

Continuous administration of thiouracil or thyroid removal decreased the body temperature of both rabbits and rams, but the decrease was prevented by thyroxine. It is suggested that the fall in temperature resulted from a lower metabolic rate.—W. A. Greig.

ROWINSKI, P. and MANUNTA, G. La termoregolazione verso il caldo nella cavia ipotiroidea per trattamento con metiltiouracile. [Thermoregulation against cold in the guinea pig rendered hypothyroid by treatment with methylthiouracil.] *Arch. Sci. biol., Bologna*, 1954, 38, 206-220. [Ist. Fisiol., Fac. Med. Vet., Univ. Sassari.]

Of 4 pairs of guinea pigs 2 of each sex served as control and the other 2 received methylthiouracil; after 63 days of treatment with methylthiouracil the 2 females had their thyroids removed. Basal

N.A. and R., January 1955

metabolism at different environmental temperatures was estimated by Haldane's method with open circuit.

Adaptation to cold was not impaired by methylthiouracil, though basal metabolic rate was somewhat less than in controls, especially in the males. Water loss at temperatures between 30° and 40° C. was decreased in males and increased in females by methylthiouracil.

Adaptation to cold was abolished by removal of the thyroid.—D. Duncan.

684

KENSHALO, D. R. Maternal hypo- and hyperthyroidism in albino rats as influencing growth, metabolism and endocrine gland weights of the offspring. *Growth*, 1954, 18, 13-26. [Florida State Univ.]

Female rats, 90 to 120 days old, were divided into 3 groups; 31 were rendered hypothyroid by total or subtotal thyroid removal and 22 received thyroxine daily by injection. The smallest dose given was 2.1 times the amount normally secreted by the thyroid of a pregnant rat and the largest dose was 13.4 times that amount. The injections were stopped 2 days before parturition. The controls were untreated. All the females were mated with males of the same age. After birth the litters were reduced to 6 young in each litter; they were weaned at 4 weeks. The standard diet was Purina Laboratory Chow. Food consumption and basal metabolism were recorded. At 33 weeks the offspring were killed and pituitary, thyroid and adrenal glands, gonads and seminal vesicles were weighed.

No difference was found in growth, food consumption or oxygen consumption in the offspring of these rats, but at 33 weeks the adrenals of daughters of hyperthyroid dams and the adrenals and ovaries of daughters of hypothyroid dams were significantly heavier than those of controls.

HARKNESS, M. L. R., HARKNESS, R. D. and SANTLER, J. E. Changes in the collagen content of the thyroid in rats treated with thiouracil. *J. Physiol.*, 1954, 125, 51-55. [Dept. Physiol., University Coll., London.]

Thiouracil was administered to rats in the drinking water at 0.05 per cent, w/v. The 4 rats in each group were killed 3, 6, 12, 24 or 50 days after thiouracil treatment began. The average

thyroid gland weight increased from 18.0 mg. \pm 2.5 in the controls to 58.4 mg. \pm 4.5 at 50 days. The total collagen in the thyroids increased from 0.369 mg. \pm 0.068 to 0.886 mg. \pm 0.075 in the same time. After the thiouracil treatment ceased, collagen decreased and the weight of the thyroids fell. The disappearance of collagen was fairly rapid during the first 30 days but after the 37th day it was much slower.—B. W. Simpson.

687

MELLEN, W. J. and HILL, F. W. Basal metabolism and thyroid size in chickens fed thiouracil and a thiouracil-thyroprotein combination. *Poultry Sci.*, 1954, 33, 872-874. [Dept. Poultry Husb., Cornell Univ., Ithaca, N.Y.]

Groups of 40-day-old male chickens were given an adequate basal starting ration with supplements of 0.2 per cent. thiouracil with or without 1 g. thyroprotein per 100 lb. feed. Mean live-weights at 3 to 3½ weeks were 139 g. and 180 g., respectively. Measurements of basal oxygen consumption during the period 3 to 3½ weeks of age indicated that there was no difference between the groups when the values were adjusted for live-weight. The weight of the thyroids of birds from groups 1 and 2 were 290 g. and 346 g., respectively, after adjustment for liveweight.—M. J. Head.

688

LIBBY, D. A. and MEITES, J. Negative effects of antibiotics on thyroid gland. *Science*, 1954, 120, 354. [Dept. Physiol., Michigan State Coll., East Lansing.]

Immature male rats in 3 groups of 10 were fed for 21 days on a basal diet alone or with 50 mg. potassium penicillin G or 50 mg. aureomycin per kg. diet. On the 21st day, 16 hr. before being killed, each rat was injected intraperitoneally with 1.0 μ C. ¹³¹I. Neither penicillin nor aureomycin altered the size of the thyroids or their uptake of ¹³¹I.

White Leghorn cockerels aged 20 days were divided into 3 groups of 10 each and fed on a diet alone or with 90 g. arsenic acid or 2 g. penicillin per ton. After 5 weeks the chicks were killed and the thyroids were weighed. Neither substance influenced the weight of the thyroid. These findings are not in agreement with those of Calesnick *et al.* (Abst. 3241, Vol. 24).—B. W. Simpson.

690

SOLIMAN, F. A. and REINEKE, E. P. **Changes in uptake of radioactive iodine by the thyroid of the rat during the estrous cycle.** *Amer. J. Physiol.*, 1954, 178, 89-90. [Physiol. Dept., Fac. Vet. Med., Univ. Cairo.]

The oestrus pattern of each of 35 mature female rats was studied for 5 days. Each animal was then injected intraperitoneally with 1 μ C. of ^{131}I and killed exactly 6 hr. later. The thyroids and other organs were weighed and radio-activity counts were made to estimate the uptake by the thyroids during pro-oestrus, oestrus, metoestrus and dioestrus. Iodine concentration by the thyroid was at its maximum during oestrus, decreased at metoestrus and reached the lowest levels at dioestrus and pro-oestrus. In a second test, where I intake was rigidly controlled, 43 rats were treated in the same way, with the same result.

In further experiments oestrogens in small doses consistently increased thyroid I; progesterone had the opposite effect. It is suggested that the rhythmic alteration in the thyroid during the oestrus cycle is probably controlled by changes in the levels and proportions of oestrogen and progesterone secreted by the ovary.—B. W. Simpson.

691

ASCHKENASY, A. **Action de la testostérone, de la thyroxine et de la cortisone sur l'ingestion alimentaire, la chute de poids et l'état des organes chez le rat carencé en protéines. [Effect of testosterone, thyroxine and cortisone on food consumption, weight loss and the state of the organs in the rat on protein-deficient diet.]** *Ann. Endocrinol.*, 1953, 14, 353-365.

Five control rats received a diet containing 18 per cent. casein and 5 experimental groups of from 4 to 10 rats received a similar but protein-free diet. Rats of different groups received testosterone propionate or thyroxine or cortisone or all 3 hormones. After 35 days all were killed for study of the carcasses.

The progressive decrease in appetite seen in the rats on protein-free diet was enhanced by the hormones. The loss of weight was greatest in rats receiving cortisone or all 3 hormones. In protein-starved rats not all organs lost the same proportion of their weight; the loss of parietal fat and the muscular atrophy led to increased relative weights of liver, kidneys, testicles, adrenals and thyroid. The spleen, thymus and accessory sex glands became greatly reduced in relative weight. Testosterone increased the loss of weight of the carcass, liver, spleen, lymphatic tissue and

thymus, but the kidneys, adrenals, testicles and thyroid were relatively large and the seminal vesicles and preputial glands very large. Thyroxine did not greatly affect the loss of carcass weight or of liver or kidney tissue, but it sometimes protected the spleen, thymus and preputial glands, while the testicles became very small. Cortisone increased the loss of liver tissue, but partly masked this by an increase in its water content. There was no effect on the kidneys or accessory sex glands, but the thyroid was larger than in any other group. All 3 hormones together had much the same effect as testosterone alone, except that the liver lost less weight. The histological changes are described.—D. Duncan.

692

GRIFFIN, A. C., LUCK, J. M., KULAKOFF, V. and MILLS, M. **Further observations on the endocrine regulation of blood amino acids.** *J. Biol. Chem.*, 1954, 209, 387-393. [Dept. Chem., Stanford Univ., Calif.]

When intact rats were injected with adrenaline, pituitary growth hormone, insulin or pituitary thyrotropin, but not after *l*-noradrenaline bitartrate, blood amino-N fell to about 90 per cent. of the pre-injection value 1 hr. after administration and to 88 per cent. after 2 hr., with recovery to 92 per cent. after 4 hr. The blood amino-N of hypophysectomised rats was reduced by all 5 hormones; recovery was slower. With adrenalectomised rats, low blood amino-N was found after injection of adrenaline and to a slight extent after growth hormone, insulin and thyrotropin. No effect was found with *nor*adrenaline or with adrenocortical steroids and sex hormones. It is concluded that adrenaline is one of the final effector substances in producing low blood amino-acid values, and that thyroid function may also be involved.

693

ASSALI, N. S. and SUYEMOTO, R. **Studies on toxemia of pregnancy. Effects of corticotrop hormone (ACTH) on the hemodynamics and the excretion of electrolytes of normal pregnant women.** *Metabolism*, 1954, 3, 303-312. [Obstet. Res. Lab., Univ. Cincinnati.]

Three pregnant women without hypertension or other abnormality of pregnancy were given ACTH intramuscularly in doses of 120 to 140 mg. daily for 4 to 6 days. Observation extended from 3 days before treatment until 3 days after completion of treatment. ACTH had no effect on blood pressure, or on the response of blood pressure to ganglionic blockade with tetraethylammonium chloride, and there was no evidence of water retention. Na excretion tended to fall and plasma Na to rise, K excretion to rise and plasma K to fall.

N.A. and R., January 1955

It was concluded that pregnancy toxæmia cannot be attributed to hyperactivity of the adrenals.

A. M. Thomson.

694

COMSA, J. Nouvelles recherches sur l'interaction thymus-thyroïde-gonades chez le cobaye. [New researches on the interaction of thymus, thyroid and gonads in the guinea pig.] *J. Physiol., Paris*, 1954, **46**, 577-583.

The gonads and thymus were removed from male guinea pigs weighing about 180 g. and experiments were made 70 days later. Some of the animals received injections of thymus extract and others testosterone propionate.

The removal of gonads and thymus resulted in hyperactivity of the thyroid, as suggested by histological examination of the thyroid, high thyrotropic activity in the urine, low blood cholesterol and high urinary creatine. All these signs were reduced or abolished by 4 daily injections of thymus extract or testosterone.—D. Duncan.

APPEL, W. and HANSEN, K. J. Über den Abfall der veresterten Fettsäuren und der Aminosäuren des Blutes nach Insulin. [Decrease of esterified fatty acids and of amino-acids in the blood after insulin.] *Hoppe-Seyler's Ztschr.*, 1954, **297**, 49-60. [Med. Klin., Univ. Kiel.]

The first effect of insulin on the blood was a decrease in the blood fats, followed by the effect on the blood sugar, and by a fall in the amino-N with further increase of the dose. Whether given subcutaneously or intravenously, insulin caused a reduction in the esterified fatty acids of the serum, in a dose which was still without definite effect on the blood sugar. The decrease was mainly in the neutral fats; the amounts of lipid P and cholesterol ester showed no appreciable change. Simultaneous administration of insulin and dextrose showed that the decrease of the esterified fatty acids and amino-N of the serum bore no relation to the blood sugar content, but depended on the dose of insulin. This indicates that the decrease was not caused by changes in the carbohydrate metabolism, but was a direct effect of the insulin, which might be due to acceleration of the active transport

of these substances into the cell through the cell membrane. It is assumed from these results that insulin promotes the formation of protein and fat not only indirectly through its effect on carbohydrate metabolism, but also directly by increasing the amounts of the necessary components in the tissues.—M. B. Richards.

PERLOFF, W. H., LASCHÉ, E. M., NODINE, J. H., SCHNEEBERG, N. G. and VIEILLARD, C. B. The starvation state and functional hypopituitarism. *J. Amer. Med. Assoc.*, 1954, **155**, 1307-1313. [Endocrine Clin., Philadelphia Gen. Hosp., Pa.]

Studies of endocrine function were made in 5 undernourished patients, 3 women with *anorexia nervosa* and 2 men with diagnoses of non-tropical sprue and of emotional depression with anorexia, respectively.

All the women had amenorrhoea with low urinary oestrogen output and no measurable gonadotropins, indicating ovarian failure secondary to lack of pituitary stimulation. All patients had low excretions of 17-ketosteroids and one man had also a low gonadotropin output, but the patient with sprue had a high gonadotropin output. Two patients had normal uptakes of ¹³¹I by the thyroid, but in 2 the uptake was borderline and in the man with sprue it was very low even when the isotope was given intravenously.

The B.M.R. was low in 3 patients and the blood cholesterol level was also low in 3; the latter constitutes an important difference from hypopituitarism. Low 17-ketosteroid excretion, low serum chloride level, impaired eosinophil responses after administration of insulin, adrenaline or corticotropin, and low blood sugar levels in several patients were suggestive of impaired adrenocortical function.

It is suggested that all the changes described were due to pituitary insufficiency, though the one woman who died had a pituitary of normal size and structure. In the other patients re-feeding restored all the functions to more normal levels. The difficulty of differentiating the condition from hypopituitary cachexia is discussed. The ultimate diagnosis probably depends on the response of the malnourished patient to re-feeding; the hypopituitary patient usually requires endocrine therapy.—D. Duncan.

- NICKERSON, K., BONSNES, R. W., DOUGLAS, R. G., CONDLIFFE, P. and DU VIGNEAUD, V. Oxytocin and milk ejection. *Amer. J. Obstet. Gynecol.*, 1954, **67**, 1028-1034. [Dept. Obstet. Gynaecol., Cornell Univ. Med. Coll., New York.]

Women 4 to 8 days *post partum* received by injection, immediately before a nursing, either naturally occurring oxytocin, highly purified and containing no detectable vasopressin, or a synthetic octapeptide amide which is, as far as has been tested, identical with the natural substance. Milk ejection occurred consistently after the intravenous injection of 0.5 unit or the intramuscular injection of 2 units. The milk flow generally lasted for less than a minute. The only side effect noted was painful uterine contractions in one woman.

That synthetic oxytocin was indistinguishable from the naturally occurring substance is taken as proof that both oxytocic and milk-ejection activities are inherent in the molecular structure.

There is a historical review of the literature.

- RODRÍGUEZ, R. R. Alloxan diabetes in the rat: recovery following estrogen treatment. *Endocrinology*, 1954, **55**, 1-9. [Inst. Biol. Med. Exp., Costa Rica 4185, Buenos Aires.]

In rats made diabetic with alloxan and forcibly fed, prolonged treatment with oestradiol benzoate, alone or with insulin, was curative. In the 6 months of observation 26 per cent. of the untreated rats died and the rest remained diabetic. Administration of insulin in amounts sufficient to prevent glycosuria reduced the mortality to 3 per cent. but did not cure the diabetes, the insulin requirement remaining unchanged throughout at 7.3 units on the average. Treatment with oestradiol alone, 15 µg. daily, cured 47 per cent. of the rats, after initial exacerbation of the diabetes, when several animals died. Combined treatment with insulin and oestradiol cured 69 per cent. of the rats, the regression of the diabetes being accompanied by a decrease in the insulin requirement from 7 units to none in 3 to 4 months. The curative action was confirmed by histological examination of the pancreas.—M. B. Richards.

- LAMB, M. W. and MICHIE, J. M. Basal metabolism of nineteen children from two to ten years old. *J. Nutrition*, 1954, **53**, 93-104. [Dept. Foods Nutrit., Texas Technol. Coll., Lubbock.]

The subjects were 9 girls and 10 boys aged from 2 to 10 years, healthy and of normal growth. Oxygen consumption was studied with a Collins Benedict Roth apparatus; the children were lying quietly awake, 12 to 14 hr. after their last meal. Results of 86 experiments are given.

The B.M.R. was more closely related to growth in height than to that in weight or in surface area.

Calories per kg. bodyweight were inversely proportional to age, but calories per cm. height were independent of age. Results were more uniform for girls than for boys. The results are compared with predictions from 5 standards; Benedict height, Dreyer, Talbot height, Talbot weight and Lewis. The best correlation was obtained with the Lewis standards; of the 86 results only 4 deviated from the Lewis prediction by 10 per cent. or more. For girls the average was slightly below and for boys slightly above the Lewis standard. Agreement with Talbot's standards was also good, the results being about 9 per cent. above these standards.—D. Duncan.

- NARANJO VARGAS, P., CORNEJO, F. and BERMEO, J. El metabolismo basal en la embarazada y el feto. [Basal metabolism in pregnancy and in the foetus.] *Rev. española Fisiol.*, 1953, **9**, 221-241. [Fac. Med., Univ. Central Ecuador, Quito.] English summary.

In 40 clinically healthy non-pregnant women in Ecuador, aged from 17 to 40 years, the mean

N.A. and E., January 1955

B.M.R. as estimated with the MacKesson apparatus was $+0.42$ per cent. on the DuBois standard, standard error ± 6.71 . There was no change with age.

In 200 pregnant women within the same age limits there was a linear increase in B.M.R. as pregnancy progressed; the mean value rose from $+5.5$ per cent. ± 8.6 at 8 weeks to $+48.6 \pm 12.6$ at 36 weeks of pregnancy, and this was also independent of age. In 32 observations during the puerperium the B.M.R. fell to $+0$ in 8 or 9 days after parturition.

From the results a table of standard B.M.R. values during pregnancy and the puerperium is presented. The mechanism of the changes is discussed in the light of the observations that arterial blood pressure, pulse and respiratory rates were unchanged. The surface area and corresponding energy requirement of the foetus are calculated from existing data and it is estimated that of the "standard" increase in B.M.R. of 41.2 per cent. at the end of pregnancy, about 12.7 per cent. corresponds to the needs of the foetus and 28.5 per cent. to those of maternal and placental tissues.

MAHADEVA, K. The energy expenditure at rest of Southern Asiatics in Britain. *Indian J. Med. Res.*, 1954, 42, 181-190. [Dept. Physiol., Univ. Edinburgh.]

Energy exchange was measured in 20 healthy South Asiatic men aged between 20 and 41 years after residence in Scotland for periods of from 1 month to 4 years. The same number of healthy Europeans served as controls. Measurements were made with a Benedict Roth spirometer and with the subjects resting about 1 hr. after a light morning meal. Deviations from basal rates by the Robertson and Reid standard (Abst. 2278, Vol. 22) were calculated. The mean values for the groups, the South Asiatic given first, were, age 30.7 , 29.0 years; weight 63.4 , 68.4 kg.; height 168.5 , 175.2 cm.; surface area 1.72 , 1.83 sq. m.; energy expenditure 40.1 , 40.6 Cal. per sq. m. per hr.; deviation from predicted basal rate $+9.9$, $+10.6$ per cent. The energy expenditure by the 2 groups did not differ significantly.

The influence of climate on resting metabolism is discussed.—D. Harvey.

BALKE, B. Optimale körperliche Leistungsfähigkeit, ihre Messung und Veränderung infolge Arbeitsermüdung. [Optimum bodily performance, its measurement and modification as the result of fatigue.] *Arbeitsphysiologie*, 1954, 15, 311-323. [Sch. Aviation Med., Randolph Field, Tex.]

The view is now held by physiologists that neither strength nor speed nor endurance determines work capacity but "the total work load that gives functionally optimal or maximal output". This may be estimated by finding the limits of performance at 3 loads and extrapolating, or by increasing the load at regular intervals until recognisable criteria of fatigue appear. The latter technique was used with an electrically braked bicycle ergometer or a moving plane the incline of which could be increased by a known amount at short intervals. Recorded were blood pressure, pulse rate, rate of respiration, respiratory volume, alveolar oxygen and carbon dioxide tensions, oxygen consumption and carbon dioxide production. Oxygen in expired air was recorded at 15-sec. intervals from a Pauling oxygen meter and carbon dioxide was continuously recorded by an infrared apparatus on a photokymograph, calibrated by analysis in a Haldane apparatus of samples collected at intervals in a Douglas bag. The load was increased until pulse rate reached 184 to 188 beats per min. or a fall of systolic pressure indicated failure of the circulation to achieve further adaptation.

When the oxygen used per pulse beat begins to decline while work continues, the optimum has been passed; also when carbon dioxide production exceeds oxygen consumption. At these critical points hyperventilation appears; alveolar oxygen tension rises and carbon dioxide falls. These criteria point to maximum sustained output at a pulse rate of 180 per min.

With work of medium to heavy intensity, even one hour produces fatigue and after a rest the same level of output is not attained. All the criteria of performance are affected by fatigue.—I. Leitch.

PAGÉ, É. and CHÉNIER, L. P. Effects of diets and cold environment on the respiratory quotient of the white rat. *Rev. canad. Biol.*, 1953, 12, 530-541. [Dept. Physiol. Nutrit., Fac. Med., Laval Univ., Quebec.] French summary.

The respiratory quotient was measured at 5° and 29° C. in male Wistar rats after 3 weeks on a complete diet high in fat, which in a total of 128.6 parts included casein 24, sucrose 17, and fat 50, or after a shorter time on a diet low in fat which included, per cent., casein 15, sucrose 78 and fat 1. Some of the rats were adapted to cold for 3 weeks at a temperature of from 8° to 10° C.

Measurements were made fasting or after a dose of 1 ml. maize oil or 1 ml. 33 per cent. maltose solution per 100 g. bodyweight.

Exposure to cold depressed the R.Q. whatever the previous experience of diet or temperature. Administration of maltose caused the R.Q. to increase in all circumstances of temperature, but oil had no effect. In rats not adapted to cold the R.Q. was lower in those on the high-fat diet; the effect was the same, but less, in rats adapted to cold. In rats kept at 29° C. and fed on a low-fat diet, adaptation to cold led to a lower R.Q. than in rats not so adapted. With a high-fat diet, adaptation made no difference.

The oxygen consumption of the same rats was about doubled by exposure to cold, and adaptation to cold also increased it at 29° C. but not at 5° C. Diet had little effect except that administration of maltose or oil to non-adapted rats given the low-fat diet depressed oxygen consumption.

Fasting rats were more active than rats given oil or maltose.

It is suggested that rats exposed to cold burn fat preferentially and that adaptation to cold is characterised by preferential utilisation of fat and accelerated conversion of sugar to fat.

CHÉNIER, L. P. Effet du froid et des régimes alimentaires sur les échanges respiratoires du rat blanc. [Effect of cold and diet on respiratory exchange in the white rat.] *Laval méd.*, 1954, 19, 241-267 (to be continued). [Dept. Physiol. Nutrit., Inst. Physiol., Laval Univ., Quebec.]

The thesis includes a general review of the subject.

Male Wistar rats were maintained on a diet high in fat or on one high in carbohydrate; the diets were not identical in every other particular. Oxygen consumption and rectal temperature were measured in the rats fasting after 1 hr. at 0° C. and after 1 and 2 hr. at -20° C. Some of the rats were previously exposed for 2 weeks to a temperature of from 1° to 2° C. In the rats not previously adapted to cold, oxygen consumption rose with declining temperature in the same way in both dietary groups, but rectal temperature was better maintained with the high-fat diet. In the rats adapted to cold for 2 weeks previously and then exposed for 2 hr. at -20° C., the oxygen consumption of those having the high-fat diet was significantly the greater; the rectal temperature was the same for both diets. The rats on the high-fat diet had throughout less tendency to lose weight.—E. M. Hume.

718

SELLERS, E. A., YOU, R. W. and MOFFAT, N. M. Regulation of food consumption by caloric

N.A. and R., January 1955.

value of the ration in rats exposed to cold. *Amer. J. Physiol.*, 1954, **177**, 367-371. [Dept. Physiol., Univ. Toronto.]

In 2 sets of experiments the effects of keeping rats in individual cages at $1.5 \pm 1^\circ \text{C}$. were studied. In the first 6 experiments diets and treatments varied; at different times 6 diets were given, in all of which protein content was 20.5 g. but fat ranged from 5.5 to 44.5 g., carbohydrate from 42.5 to 67.5 g. and energy from 412 to 615 Cal. per 100 g. The average daily intake by survivors varied widely from 13.8 to 23.9 g., the amount ingested being less with the high than with the low fat content, but the energy intake was remarkably constant, mostly between 80 and 90 Cal. There was no difference in survival for the groups which could be attributed to the fat content of the diets.

The findings in 2 more experiments confirmed the results of the first. When the diet was high in fat the amount of food and consequently of protein consumed was less than when a diet low in fat was taken; the urinary output of N varied in the same way.—D. Harvey.

719

MELLEN, W. J., HILL, F. W. and DUKES, H. H. Studies of the energy requirements of chickens. 2. Effect of dietary energy level on the basal metabolism of growing chickens. *Poultry Sci.*, 1954, **33**, 791-798. [Agric. Exp. Stat., Cornell Univ., Ithaca, N.Y.]

The 3 basal rations contained all known dietary constituents, and the energy values were varied to 975, 623 or 505 Cal. per lb. by altering the proportions of ground grain and ground oak husk.

In experiment 1, groups of 32 male day-old Rhode Island Red \times Barred Plymouth Rock chickens were given the high- and low-energy feeds. At 4 weeks of age both groups weighed the same, although the energy intake of the low-energy group was two-thirds that of the other. At $4\frac{1}{2}$ weeks of age, the oxygen consumed by the high-energy birds was 0.575 litre per bird per hr., which was significantly higher than the value of 0.465 recorded for the low-energy group.

In experiment 2, separate male and female groups of 20 Barred Plymouth Rock \times Rhode Island Red day-old chickens were given the high- and medium-energy rations. B.M.R. measurements were made on males at 5 to 6 and 14 to 17 weeks of age and on females at 9 to 10 and 19 to 22 weeks. The slightly higher oxygen consumption of birds on the high-energy ration was consistent, but not statistically significant. The experiment was repeated using the high- and low-energy rations and B.M.R. measurements were made at 4 to 6 weeks of age. Both males and females receiving the high-energy feed were heavier at the time of B.M.R. measurement. There was no

statistically significant difference in B.M.R. due to treatment, sex or sex-treatment interaction. Separate analysis of data for each sex indicated that for males only there was a significantly greater oxygen consumption by the birds receiving the high-energy ration.

Statistical analysis indicated that females had larger thyroid glands relative to bodyweight than males.—M. J. Head.

HASAN, J. and NIEMI, M. Metabolic responses of human subjects to severe acute thermal stress. *Acta physiol. scand.*, 1954, **31**, 137-146. [Inst. Occupational Health, Helsinki.]

Observations were made of oxygen consumption, rectal and skin temperatures and pulse rate in 16 human subjects during and after exposure to extremely high environmental temperatures in a Sauna bath. Most of the subjects showed a rise in the metabolic rate during thermal stress, with a subsequent fall, but no decrease in the metabolic rate below the pre-heating level could be found during the first hour, at 10 hr. or at 18 hr. after the thermal stress. The atypical reactions observed in 3 subjects might possibly be explained on an emotional basis. Positive correlations were observed between the metabolic rate and rectal temperature, skin temperature and pulse rate.

M. B. Richards.

722

HASAN, J., LAAMANEN, A. and NIEMI, M. Effect of thermal stress and muscular exercise, with and without insulin hypoglycaemia, on the body temperature, perspiration rate, and electrolyte and lactate content of sweat. *Acta physiol. scand.*, 1954, **31**, 131-136. [Inst. Occupational Health, Helsinki.]

The effect of low blood sugar, induced by insulin injections, on the rise in body temperature, perspiration rate, and electrolyte and lactate content of sweat, produced by thermal stress in a Finnish Sauna bath or by exercise on a treadmill, was studied on 10 soldiers and 9 students of physical education. Low blood sugar caused no significant difference in the perspiration rate or in the electrolyte content of sweat, but the lactate content showed some tendency to increase with decreased blood sugar concentrations. The rise in body temperature was significantly smaller than in

experiments without insulin injections. The Na content of sweat was significantly higher in the students than in the soldiers; this may indicate that the former were in a state of adrenocortical insufficiency caused by overtraining.

M. B. Richards.

JOLIET, J. F. and CASTILLON DU PERRON, M. Sur l'élimination de l'eau par les voies respiratoires. [Elimination of water by the respiratory tract.] *C.R. Acad. Sci.*, 1954, 239, 620-622.

By means of a simple apparatus the amount of moisture in the expired air of healthy subjects was weighed, and related to the intake of oxygen. For 1 ml. oxygen consumed, elimination of water was almost constant. The figures for 8 subjects ranged from 0.59 to 0.68 mg. water, 2 to 5 estimations being made on each subject. By this method it is possible, under normal conditions, without correction for temperature or pressure, to measure the quantity of oxygen absorbed with a precision at least equal to that of the usual apparatus for measuring metabolism.—M. B. Richards.

725

LEBLANC, J. Subcutaneous fat and skin temperature. *Canad. J. Biochem. Physiol.*, 1954, 32, 354-358. [Defence Res. Med. Labs., Toronto, Ont.]

Skin temperatures were taken at 20 places on the trunk of 6 young men after exposure for 20, 40 and 60 min. to air temperatures of 50°, 60° and 70° F.

The rate of fall of skin temperature was greatest in the first 20 min. and was also affected by the environmental temperature [the text says that the fall was faster at 70° than at 50°, but this does not agree with the figures in Table 2]. No subject shivered at 70°, and at this temperature there was no apparent effect of subcutaneous fat thickness. At 60° and at 50° the mean fall in skin temperature and the onset of shivering were related to the

thickness of subcutaneous fat. Regional variations in fat thickness in the same subject were also related to differences in skin temperature over the body.—D. Duncan.

726

PATCHELL, M. R. Direct effects of climate on cattle. 1. Some observations on the skin temperature, body temperature, respiration rate and pulse rate of dairy stock under normal temperature conditions. 2. Measurements of skin temperature in cattle. *N.Z. J. Sci. Technol.* [A], 1954, 36, 1-9; 10-14. [Dairy Res. Inst. (N.Z.), Palmerston North.]

1. The body and skin temperatures, respiration rate and pulse rate of 6 pairs of 2-year-old identical twin Jersey heifers were recorded at air temperatures of from 36° to 67° F. Records were made 4 times daily on 3 days in every fortnight for 3 months.

Statistical analysis of the results showed that respiration rate and skin temperature increased when air temperature rose. Differences between animals in body temperature and pulse rate were believed to be due to the effect of pregnancy. Twin pairs tended to have similar respiration and pulse rates.

2. Four types of thermocouple for taking skin temperatures in cattle are described and their advantages and disadvantages are discussed. With this type of instrument more accurate readings were obtained when the hair was left on than when it was shaved. Skin temperatures were lower on the extremities than on the trunk.—J. N. Aitken.

KNAPP, B. J. and ROBINSON, K. W. The role of water for heat dissipation by a Jersey cow and a Corriedale ewe. *Austral. J. Agric. Res.*, 1954, 5, 568-577. [Sir William Macgregor Sch. Physiol., Univ. Queensland, Brisbane.]

The animals were exposed 12 times to controlled environmental conditions in a psychrometric room. Each exposure lasted 7 hr. Six exposures were made with varying dry bulb temperature in steps of 4.5° through a range of 86° to 108.5° F. at a fixed humidity of 30 mm. Hg vapour pressure. The other exposures were made with varying humidity in 5-mm. steps over the range 15 to 40 mm. Hg vapour pressure at a constant temperature of 104° F. Air movement was constant.

Rectal temperature and respiratory rate and volume of both animals increased during exposure to heat. The sheep was more severely affected than the cow when both temperature and humidity were high.

Water loss through the skin of the Jersey cow

N.A. and B., January 1955

was of the same order as loss through human skin. Respiratory water was only a fifth to a ninth of the total water lost. In the sheep transectaneous water loss was only a third of that through human skin. Respiratory water losses accounted for a third of the total.

It was concluded that the more efficient heat-regulating mechanism of the Jersey cow would enable it to withstand extreme environmental conditions better than the Corriedale ewe. An apparatus for measurement of respiratory volume and vapour pressure of expired air is described.

CALCAGNO, P. L. and RUBIN, M. I. (with KELLEHER, M. K. and STUBBINS, M. M.) Effect of added carbohydrate on growth, nitrogen retention and renal water excretion in premature infants. *Pediatrics*, 1954, 13, 193-202. [Statler Res. Labs., Child. Hosp., Buffalo, N.Y.] Spanish summary.

The effect of adding carbohydrate to a diet of evaporated milk and water was tested in a group of 4 infants for whom the diets with and without added carbohydrate were isocaloric and in a group of 5 infants for whom the diets with and without added carbohydrate were of equal N content. Balance studies were made in 4- to 6-day periods with foreperiods of 5 to 7 days before each diet.

In both groups the average daily weight gain was greater when carbohydrate was added to the diet. In the isocaloric diet group average N, Na and K retentions were greater on the diet which contained higher levels of these nutrients. With constant N intake the average N, Na and K retentions were greater and blood urea N and daily

urea excretion were lower when energy intake was increased by addition of carbohydrate to the diet. In both groups average total electrolyte excretion was lower with added carbohydrate. With constant energy intake urine volume was greater and with constant N intake it was less when extra carbohydrate was given.—F. C. Aitken.

733

RODRÍGUEZ MIÑÓN, J. L., JIMÉNEZ DÍAZ, J. and DE GÓRGOLAS, R. Changes in the carbohydrate tolerance in patients with renal disease. *Bull. Inst. Med. Res., Univ. Madrid*, 1953, 6, 97-104. [Med. Clin.]

In double blood sugar tolerance tests 10 out of 14 patients with nephritis showed curves of diabetic type when given glucose by mouth. In another 8 patients glucose given by vein produced higher blood sugar values and longer disappearance curves than were seen in 3 normal subjects. The disturbance in utilisation of glucose suggests participation of the kidney in carbohydrate metabolism.—D. Duncan.

HJORT, P. On the glucose tolerance test in sprue. *Acta med. scand.*, 1954, 149, 119-126. [Med. Dept. A., Rikshosp., Oslo.]

The effect of the amount of carbohydrate in the diet on the flat curve produced by oral glucose tolerance tests in sprue was studied in 3 subjects. Reduction of the carbohydrate content of the diet had the effect of raising and broadening the tolerance curve in 2 subjects; in the other the curve was flat even on a low-carbohydrate diet. The

high broad curve of a diabetic with sprue is shown also. Intravenous glucose tolerance tests in 2 of the patients with sprue showed on normal diet high curves which became higher and broader after a low-carbohydrate diet.

The findings are thought to be consistent with the theory that reduced glucose absorption causes the flat curves.—F. C. Aitken.

KÖNIG, A. Beitrag zur Frage der Blutzuckerregulation nach intravenösen Dextrosebelastung. [Blood sugar regulation after intravenous dextrose.] *Ztschr. ges. exp. Med.*, 1954, 124, 93-105. [Inst. Physiol., Univ. Greifswald.]

Blood sugar estimations hourly for 10 hr. on normal rabbits gave curves which differed widely in different animals and were of 3 types: hyper-regulatory, with variations of more than 30 mg. per cent. in the course of the day; average, with variations from 15 to 30 mg. per cent.; and hypo-regulatory, with variations below 15 mg. per cent. Within a few seconds after intravenous injection of glucose, glucose in the blood fell, after 1 min. to 48 to 73 per cent. of the initial value. Two explanations are discussed, immediate diffusion of the sugar into the interstitial tissues, or combination of the sugar with serum colloids. The height of the peak was independent of the original blood sugar value, and showed no direct proportionality to the dose injected. Immediately after injection of glucose there was dilution of the blood which was followed by diuresis. After loading with different amounts of glucose, the curves differed only in the magnitude of the variations. The curves were individually characteristic for different animals.—M. B. Richards.

FRANÇOIS, R. and RUTON-UGLIENGO. Acidose et utilisation des hydrates de carbone. Application au traitement des états de déshydratation. [Acidosis and carbohydrate utilisation. Application to the treatment of states of dehydration.] *Presse méd.*, 1954, 62, 867-869. [Lyons.]

In dogs with acidosis induced by intravenous perfusion with NH_4Cl the injection of insulin was followed by a much smaller fall in blood sugar and in plasma K and inorganic P levels than in the same dogs in their normal state. Acidotic dogs also showed a diabetic response to a glucose tolerance test. Utilisation of plasma glucose *in vitro* by red blood cells was inhibited by acidification, and was less in blood taken from acidotic dogs than in normal blood. Further experiments confirmed that acidosis interferes with the action of insulin.

In an infant of 11 months, severely dehydrated as a result of digestive disturbance, infusion of isotonic glucose in serum was ineffective in restoring the plasma electrolyte balance; it is concluded that the acidosis prevented the uptake of glucose by the red cells and that the glucose increased the osmotic pressure of the plasma, forced diuresis and in fact made the situation worse. The infant died. In a second infant with similar intense dehydration the first infusion given was of 300 ml. serum with 1.2 per cent. bicarbonate to correct the acidosis, after which physiological serum and isotonic glucose quickly brought about complete recovery. The importance of correcting acidosis before administration of isotonic serum glucose solutions is stressed.—D. Duncan.

BAZHANOV, B. G. K voprosu o vliyaniy fizicheskikh upravleniia na uglevodnyi obmen bol'nykh sakharnym diabetom. [Effect of physical exercise on carbohydrate metabolism in diabetes mellitus.] *Klin. Med., Mosk.*, 1953, 31, No. 10, 80-82. [Saratov. Med. Inst.]

Changes in the level of reducing substances in the blood of diabetics were studied after injection of 5 units of insulin and again after insulin followed by exercise for 10 min. Similar estimations were made after a double load of sugar and after sugar preceded by exercise.

Except in severe diabetes, physical stress reduced the level of reducing substances in blood and in combination with insulin caused a greater fall than did insulin alone. Conversely, sugar plus physical stress resulted in a smaller rise than sugar only. Physical stress lowered reducing substances and sugar in both arterial and venous blood and increased the arterio-venous difference, changes which were relatively greater in terms of sugar than of reducing substances.—D. W. Taylor.

HILL, R., BAKER, N. and CHAIKOFF, I. L. **Altered metabolic patterns induced in the normal rat by feeding an adequate diet containing fructose as sole carbohydrate.** *J. Biol. Chem.*, 1954, **209**, 705-716. [Dept. Physiol., Sch. Med., Univ. California, Berkeley.]

Glucose tolerance tests were made on 3 groups of rats fasted for 96 hr. or fed for 3 days on an adequate diet containing 58 per cent. glucose or fructose as the sole carbohydrate. The level of plasma glucose did not exceed 130 mg. per 100 ml. in the rats fed on glucose, but in fasted rats and those fed on fructose over 250 mg. per 100 ml. was present after 5 hr.

Liver slices from rats fed on glucose or fructose were incubated with glucose, fructose or acetate labelled with ^{14}C , and the incorporation of ^{14}C into fatty acids, CO_2 and glycogen was studied. Diet made no significant difference to the production of fatty acid and CO_2 from fructose and acetate. The incorporation of ^{14}C from glucose was much less after the high-fructose than after the high-glucose diet. A similar effect was found on glycogen production from ^{14}C -glucose. Insulin injection for 3 days before rats fed on fructose were killed failed to correct the impaired oxidation of glucose.

The oxidation of ^{14}C -glucose to $^{14}\text{CO}_2$ by brain and kidney slices and the uptake of glucose from excised diaphragm of animals fed previously on glucose and on fructose were similar.

The activity of liver glucokinase was thought to be impaired by the prolonged feeding of fructose. The total concentration of hexoses in the plasma of the portal vein was about the same in rats fed on either glucose or fructose, but in rats fed on fructose the level of glucose was only slightly higher in the portal blood than in the arterial blood, while in rats fed on glucose the portal blood had twice the glucose concentration of the arterial blood. It is suggested that the glucokinase system in liver becomes adapted to dietary glucose.

STEELE, R. (with Kiyono, K. M.) **The excretion and retention of the carbon of ingested sucrose by the mouse.** *J. Biol. Chem.*, 1954, **209**, 91-103. [Dept. Biol., Brookhaven Nat. Lab., Upton, N.Y.]

Sucrose labelled with ^{14}C in both the glucose and the fructose moiety was prepared photo-synthetically.

Young adult mice were starved for 15 to 18 hr., given a priming dose of unlabelled sucrose and amino-acid solution, and 3 hr. later a similar solution with ^{14}C -sucrose. The mice were killed between $3\frac{1}{2}$ hr. and 36 days after the test dose and in the interval were fed on stock diet and kept in

metabolism chambers for collection of CO_2 , urine and faeces.

In one mouse kept for 36 days 92.1 per cent. of the ^{14}C ingested was excreted as CO_2 , 3.1 per cent. in urine and 3.2 per cent. in faeces. It was considered that when the cumulative error was allowed for the total excretion was probably more than 99 per cent. Most of the ^{14}C found in different tissues in mice killed $3\frac{1}{2}$ and $3\frac{3}{4}$ hr. after the test dose was lost rapidly, but it was concluded that the demonstration of components with rapid turnover in almost every tissue does not eliminate the possibility that a large proportion of tissue C is present in components with slow turnover.

PATTERSON, J. W. **Hyperglycemia and galactose cataracts.** *Amer. J. Physiol.*, 1954, **177**, 541-543. [Dept. Anat., Sch. Med., W. Reserve Univ., Cleveland, Ohio.]

Groups of rats weighing 94 to 117 g. received ground dog chow pellets alone or mixed with 20, 35, 50 or 65 per cent. galactose. Blood sugar was estimated weekly and development of cataracts was studied. A 5-day balance test was made on each rat.

The total blood sugar increased with galactose intake, and with it urinary galactose excretion, urine volume, water and food consumption. In spite of increased appetite rats consuming galactose ate less dog chow than controls, and weight gain decreased in proportion to dog chow consumption.

The minimum time for production of cataracts was about 14 days and the minimum blood sugar about 150 mg. per 100 ml., or an increment of 30 mg. per 100 ml. above the normal. Galactose was thus 4 or 5 times as effective as glucose in producing cataracts (Patterson, *Amer. J. Physiol.*, 1953, **172**, 77). In 4 rats given 35 per cent. galactose in the diet and injected with phloridzin twice daily to keep down the blood sugar, cataract formation was significantly slower than in pair-fed rats not receiving phloridzin.—D. Duncan.

FOURNIER, P. **Différence d'activité physiologique entre des formes isomériques du galactose. [Difference in physiological activity between isomeric forms of galactose.]** *C.R. Acad. Sci.*, 1954, **239**, 304-306.

For preceding papers see Absts. 3490-3492, Vol. 24.

The basal diet resembled those used before. Experimental diets contained 12 per cent. lactose or 6 or 20 per cent. galactose, replacing part of the starch. Each group contained 6 rats of about 50 g. bodyweight, and Ca balances and galactose excretion were studied on the third day. With lactose 57 per cent. of the Ca intake was retained, compared with 38.7 per cent. on control diet, and hardly any galactose was excreted in the urine. With 6 per cent. galactose Ca utilisation was not significantly above the control level, and half the galactose appeared in the urine. With 20 per cent. galactose Ca utilisation was 62 per cent. and again about half the galactose was excreted unchanged.

It is concluded that the favourable effect of lactose on Ca metabolism is due to the β -galactose moiety, which is well utilised. In commercial galactose there are 3 or 4 isomers, and it is supposed that only the β -galactose is effective, while the others are poorly utilised and are excreted.

ALSLEV, J. and MÖCKEL, W. Über das Verhalten der Citronensäure im Blut nach Glucose, Galaktose und Fructosebelastungen. [Behaviour of citric acid in blood after a test dose of glucose, galactose, or fructose.] *Ztschr. ges. exp. Med.*, 1954, 124, 44-51. [Med. Klin., Univ. Kiel.]

After glucose, galactose or fructose, 1 g. per kg. bodyweight, was taken in 300 ml. coffee, there followed an increase of pyruvic and lactic acid in the blood, the increase being considerably greater after galactose or fructose than after glucose, but with little difference between the 2 former. After glucose and galactose blood citric acid fell in most,

with a small increase in a few subjects. After fructose there was a regular increase in blood citric acid, although the increase was much smaller than that of pyruvic and lactic acids. The results are discussed in relation to clinical and biochemical findings reported in the literature.—M. B. Richards.

LAKSHMINARAYAN RAO, M. V. and BHATIA, I. S. Biological utilization of the polyfructosans of *Agave Vera Cruz* Mill. *Bull. Central Food Technol. Res. Inst. Mysore*, 1954, 3, 110-111.

The stem of *Agave Vera Cruz* is used as a famine food and has the percentage composition crude protein 2.9, ether extract 0.9, fibre 21, ash 2.3 and carbohydrate 72.8. The bulk of the carbohydrate consists of 2 polyfructosans, one of which was used in balance experiments with rats, growth experiments being impossible because of severe diarrhoea. From 50 to 85 per cent. of the polyfructosan was retained. The polyfructosan has a great affinity for water and the diarrhoea was attributed to absorption of water from the intestinal tissue.

PECHAR, J., DIVÍŠ, E., PLACER, Z., HÁTEL, J. and KOZLOVSKÁ, E. Vylučování dusíku stolicí. [The excretion of nitrogen in the faeces.] *Sborn. pathofysiol. tráv.*, 1954, 8, 37-43. [Inst. Nat. Nutrit., Prague.]

Nitrogen in the food, urine and faeces of more than 700 sick and healthy persons were studied. Most patients received in their diet daily 14 g. N, a few 25 g. daily. In these 2 diet groups no significant difference was found in the fresh or dry weight of faeces or in the quantity of faecal N. There was no relation between the quantities of N excreted in urine and in faeces. Faecal excretion of N was not constant even on standard diet and did not depend on the amount of N in the food.

FORSYTH, B. T. The effect of testosterone propionate at various protein and calorie intakes in malnutrition after trauma. *J. Lab. Clin. Med.*, 1954, 43, 732-740. [Army Med. Serv. Grad. Sch., Walter Reed Army Med. Centre, Washington, D.C.]

The effect of testosterone propionate on N retention was investigated in 4 patients suffering from malnutrition after severe trauma. Although the patients were in positive N balance when treatment was begun, all retained significantly more N with testosterone, though the degree of response was not clearly related to the degree of loss of lean bodyweight. The amounts of N retained on the same amount of testosterone differed in different patients, but in any one patient the additional N retention produced by testosterone was the same at different N and energy intakes, if these were adequate.—M. B. Richards.

TUI, C., KUO, N. H. and SCHMIDT, L. (with JONES, J.) The protein status in pulmonary tuberculosis. *Amer. J. Clin. Nutr.*, 1954, 2, 252-264. [Creedmoor Inst. Psychobiol. Studies, Creedmoor State Hosp., Queens Village 27, N.Y.] Spanish summary.

Nitrogen balance studies of 11 patients with advanced progressive pulmonary tuberculosis showed significantly positive balances in 4 at intakes of 40 to 60 Cal. per kg. bodyweight and 10.76 to 15.19 g. N. Two subjects were in slightly positive balance at energy intakes of 35 to 36 Cal. per kg. and N intakes of 5.43 to 6.25 g. The remaining subjects were in frankly negative balance at lower energy intakes and N intakes of 6.75 to 9.76 g. Studies of blood constituents and fluid compartments in these 11 and another patient showed presumptive evidence of low serum protein levels in 7.

The effect of a high protein intake, 50 to 60 Cal. and 0.5 to 0.72 g. N per kg., was studied in 9 of the subjects. Large positive N balances were obtained and after an initial weight loss in all except 1 subject, all gained weight. Changes in fluid compartments and blood constituents are tabulated.

The question "which is more harmful—hypoproteinaemia, which jeopardises healing because of shortage of healing material, or rapid protein replacement, which favours healing but stimulates

respiratory activity?" awaits controlled investigation.—P. C. Aitken.

756

OLESEN, K., HEILSKOV, N. C. S. and SCHØNHEYDER, F. The excretion of ^{15}N in urine after administration of ^{15}N -glycine. *Biochim. biophys. Acta*, 1954, 15, 95-107. [Biochem. Inst., Univ. Aarhus, Denmark.] French and German summaries.

The excretion of ^{15}N in the urine from 3 normal men in N balance was followed for 15 days after they were given ^{15}N -glycine. A curve given by the sum of 3 exponential terms closely fitted the experimental points in a graph of ^{15}N content of the urine against time. From the mathematical analysis of these curves it was deduced that at least four N pools, or groups of substances subject to continuous exchange of N, existed in the body, and one of these contained such a large amount of N that the amount of incorporated ^{15}N leaving it during the experiment could be neglected. Two model pool systems, simplified according to biological considerations, were mathematically solved from the data and the sizes of the pools were estimated.—C. Warner.

757

BARTLETT, P. D. and STEVENSON, A. Effects of protein anabolic hormones on rates of protein degradation and protein loss in the fasting dog. *Endocrinology*, 1954, 55, 200-204. [Edsel B. Ford Inst. Med. Res., Detroit, Mich.]

Glycine labelled with ^{15}N was given by vein to adult bitches on the second day of a fast started when the animals were in nitrogen balance. The urinary excretion of ^{15}N was studied for 5 days, during which growth hormone or testosterone propionate was given daily. Either hormone reduced the amount of ^{15}N excreted and slightly reduced the rate of protein degradation. Their effects were synergistic.—C. Warner.

STEINBOCK, H. L. and TARVER, H. Plasma protein. 5. The effect of the protein content of the diet on turnover. *J. Biol. Chem.*, 1954, 209, 127-132. [Dept. Physiol. Chem., Sch. Med., Univ. California, Berkeley.]

Rats were fed on diets containing no protein or 25 or 65 per cent. protein for 3 weeks. ^{35}S -labelled plasma protein was injected intravenously and the specific activity of the plasma was followed for 7 days. The animals receiving 25 per cent. protein had a greater average protein pool, a shorter plasma protein half-life and a greater protein replacement rate than those on the protein-free diet. This was thought to be due to quicker initial plasma protein formation. The animals on

the 65 per cent. protein diet had a slightly smaller pool, a further decrease in half-life and a slight further increase in the replacement rate compared with those on the 25 per cent. protein diet; these results were interpreted as indicating an initial increase in the rate of protein degradation.

759

FRANDSEN, A. M., NELSON, M. M., SULON, E., BECKS, H. and EVANS, H. M. **The effects of various levels of dietary protein on skeletal growth and endochondral ossification in young rats.** *Anat. Rec.*, 1954, **119**, 247-265. [Div. Dent. Med., Coll. Dent., Univ. California.]

Groups of 6 rats received from weaning diets containing no protein or 3 or 6 per cent. casein; 12 controls received a similar diet with 24 per cent. casein to appetite, and other groups of 6 received this diet but were pair-fed with littermates on the low-protein diets. The basal diet contained, per cent., alcohol-extracted casein 24, sucrose 63.5, hydrogenated vegetable oil 8, salt mixture 4 and liver eluate powder 0.5, with added vitamins. Sucrose replaced casein when this was reduced. The rats were killed at 63 to 67 days of age and skeletal growth was measured on X-ray photographs. Sections of the tibia were studied.

Skeletal growth was retarded in all the restricted groups, but always more severely in those on low-protein diets than in their pair-fed littermates. In the rats which received no casein (they received about 5 mg. N daily from the liver eluate) ossification in the tibia had ceased and "sealing-off" bone was found in the epiphysis. The marrow contained greatly distended sinusoids but no fat cells. The epiphyseal disc was narrow. The head of the tibia was small, the lamina compacta of the epiphysis was thin and the trabeculae were delicate. Similar, but less pronounced, abnormalities were present in the tibiae of all the deprived rats.

LA GRUTTA, G. and CILENTO, A. **Sostanze azotate e contenuto idrico nei ratti in crescita durante il decorso della ipoalimentazione e della successiva rialimentazione. [Nitrogenous substances and water content of growing rats during underfeeding and subsequent re-feeding.]** *Arch. Sci. biol., Bologna*, 1954, **38**, 366-376. [Ist. Fisiol. Umana, Univ. Palermo.]

Groups of young rats weighing initially 43 ± 1.2 g. were housed individually and received a synthetic diet providing, per cent., carbohydrate 75, protein 10, lipids 10 and salt mixture 5, with a multivitamin preparation. A group of 8 rats received sufficient of this diet to cover their needs for normal growth, another 8 had their intake restricted; 4 of the latter were killed when they weighed two-thirds as much as the controls, and

the other 4 were then well fed until they caught up with the controls, when all were killed.

The water content of the tissues did not differ significantly between the groups. The absolute N content of the muscles of underfed rats was maintained so that relatively to other components it increased by 9.55 per cent. ($P < 0.2$). The re-fed rats showed a mean increase of 20 per cent. ($P < 0.02$) in total N of the muscles and 50 per cent. ($P < 0.01$) in coagulable N when compared with the normal controls of the same bodyweight. The re-fed rats also showed an increase of 10 per cent. in the incoagulable N of the liver.

It is concluded that the re-fed rat can store in the muscles and liver large quantities of organic N compounds or compounds with a high proportion of N.—D. Duncan.

4. Metabolically inert lipide and protein fractions from the rat. *J. Biol. Chem.*, 1954, 203, 883-888. [Biol. Sect., Radiol. Sci. Dept., General Electric Co., Richland, Wash.]

Female rats were fed to appetite on Purina dog chow; there were 20 in the control group and 20 each received a total of 100 mC. tritium oxide intraperitoneally in 5 equal weekly injections. The rats were killed in 2 groups, at 138 and 258 days after the first injection. Samples of liver, brain, skin, fat, hind leg muscle and residual carcass were separated into protein and lipid components and the concentration of bound tritium was estimated. The biological half-life of the labelled fractions was estimated from the difference in tritium content between the groups killed early and late.

Collagen fractions showed half-lives of 300 days or longer; lipid fractions were also found with half-lives as long as 300 days. The highest concentration of bound tritium, 4 months after tritium oxide was given, was found in the lipids of brain.—G. A. Garton.

765

CANNON, P. R., FRAZIER, L. E. and HUGHES, R. H. Factors influencing amino acid utilization in tissue protein synthesis. *Nat. Vitamin Found., Inc., N.Y., Nutrit. Symposium Ser. No. 8*, 1954, 75-90. [Dept. Pathol., Univ. Chicago, Ill.]

Protein-depleted rats fed on diets of different energy content and given amino-acids by mouth or subcutaneously utilised the amino-acids for gain in weight, even when the energy intake was very low, though utilisation was best with an adequate energy intake. Riboflavin, and to some extent Ca pantothenate, pyridoxine and vitamin B₁, but not nicotinic acid or choline, was needed for good weight gain when protein-depleted rats were fed on rations adequate in energy and amino-acids.—C. Warner.

KRITZMAN [KRITSMAN], M. G. and BAVINA, M. V. Issledovanie pri pomoshchi mechenykh aminokislot intensivnosti obrazovaniya belkov organov i tkanei v norme i pri eksperimental'nom ateroskleroze. [An investigation into the rate of formation of proteins, using labelled amino-acids, in organs and tissues under standard conditions and during experimental atherosclerosis.] *Dokl. Akad. Nauk S.S.S.R.*, 1954, 94, 721-724. [Inst. Terap., Akad. Med. Nauk SSSR.]

The rate of incorporation of amino-acids into tissues of normal and atherosclerotic rabbits was studied with methionine-³⁵S, glycine-¹⁴C and tyrosine-¹⁴C. The animals were killed 8, 12, 18

Vol. 25, No. 1

and 20 hr. after intramuscular injection of the tracer and organs and tissues were analysed.

In atherosclerotic animals incorporation of methionine was much less than normal, the difference varying from 30 to 60 per cent. in the aorta to almost nil in skeletal muscle. Similar results were obtained for the other two tracers. It is considered that in atherosclerosis abnormal cholesterol metabolism should not be studied without consideration of possible abnormalities of protein synthesis.—D. W. Taylor.

NIKLAS, A., MAURER, W. and KRAUSE, H. Messung der biologischen Halbwertszeiten einzelner Serum-Eiweiss-Fractionen beim Kaninchen. (Vergleichende Messungen bei peroraler Gabe von S³⁵-Methionin und Infusion von S³⁵-markiertem Serum-Eiweiss.) [Measurement of the biological half-life of some serum protein fractions in the rabbit. Comparative measurements after giving ³⁵S-methionine by mouth or infusing serum protein labelled with ³⁵S.] *Biochem. Ztschr.*, 1954, 325, 464-476. [Med. Klin., Univ. Cologne.]

When ³⁵S-methionine was given to rabbits by mouth, the fall in the amount of ³⁵S-labelled serum protein was slower than after infusion of ³⁵S-labelled rabbit serum. The flattening of the curves after oral intake of ³⁵S-methionine was due to continuous new formation of ³⁵S-labelled serum protein, arising from the liberation in the breakdown of the labelled protein of ³⁵S-amino-acids, which were then incorporated anew into the protein. The flattening of the curves observed after ³⁵S-methionine intake can be accounted for quantitatively in this way. There was an exponential decrease in labelled albumins with a biological half-life of 10 days. The separate globulin fractions did not decrease exponentially, but more and more slowly with time, each fraction being composed of other fractions with different half-lives. The average half-life of the globulin fractions was between 2 and 5 days. In the rabbit the new formation of albumin amounted to 0.6 g. daily, and of globulins to 1.3 g.—M. B. Richards.

768

KOLFF, W. J. and PAGE, I. H. Influence of protein and other factors on postnephrectomy hypertension in rats sustained with an improved method of peritoneal lavage. *Amer. J. Physiol.*, 1954, 178, 69-74. [Res. Div., Cleveland Clin. Found., Ohio.]

Rats were prepared for peritoneal lavage by insertion of an indwelling stainless steel cannula. Peritoneal lavage had no ill effect on 2 normal rats.

After removal of both kidneys lavage was repeated 2 or 3 times daily. The rats were excessively thirsty and the water content of their tissues increased with the time of survival. Of 16 rats on mixed diets or on high-protein chow, 11 developed high blood pressure, but only 5 developed it of 21 on a low-protein, low-Na diet of rice pabulum. The blood pressure was not related to body water content, to serum Na or to the Na content of the fluid used for lavage.—D. Duncan.

MÜTING, D. Der Aminosäuregehalt des menschlichen Urins. [**Amino-acid content of human urine.**] *Hoppe-Seyler's Ztschr.*, 1954, **297**, 61-67. [Forschungsinstit. Diabetes, Karlsburg.]

Free and peptide-bound amino-acids were estimated quantitatively by paper chromatography on 24-hr. samples of urine of 40 healthy subjects. In general the values for 20 amino-acids agreed with those in the literature, but those for valine, serine and methionine were higher. No important difference was found between the urinary amino-acids of men and of non-pregnant women. The analyses seem to include the greatest part of the amino-acid content of human urine, since the sum of the amounts of α -amino-N reckoned from the separate acids studied was only about 10 per cent. less than the total content of α -amino-N found by Moore and Stein (Abst. 3939, Vol. 18).

MILLER, S., RUTTINGER, V. and MACY, I. G. **Urinary excretion of ten amino acids by women during the reproductive cycle.** *J. Biol. Chem.*, 1954, **209**, 795-801. [Res. Lab., Child. Fund Michigan, Detroit.]

Fifteen women aged from 20 to 36 years supplied 44 twenty-four-hour urine samples. Fourteen were collected during non-pregnancy, 25 during the second to ninth months of pregnancy, and 5 during lactation, 34 to 221 days *post partum*. The amino-acids were estimated microbiologically.

The quantities of amino-acids excreted fluctuated throughout gestation, but the median value for each was greater than in non-pregnancy. Threonine had the greatest percentage increase and arginine the least. During lactation each amino-acid was excreted in smaller quantities than in non-pregnancy, ranging from 49 per cent. for tryptophan to 69 per cent. for valine. The change in the excretion of amino-acids from pregnancy to lactation was most marked and threonine, lysine, histi-

dine and tryptophan fell to 7, 9, 12 and 21 per cent. of the amounts excreted during the ninth month of gestation.—A. Hepburn.

RUTTINGER, V., MILLER, S., ANDRECOVICH, M. E. and PERDUE, G. M. **Urinary free amino acid excretions during successive pregnancies.** *Proc. Soc. Exp. Biol. Med.*, 1954, **86**, 108-112. [Res. Lab., Child. Fund Michigan, Detroit.]

One woman, initially aged 23, was examined before, during and after each of her first 2 pregnancies and during part of her third, for the excretion of essential amino-acids. There was an initial increase of excretion of all these amino-acids with pregnancy, greatest for threonine, histidine, lysine and tryptophan, least for methionine. The excretion of threonine increased progressively, reaching 10 or more times the non-pregnant value, but excretion of the other amino-acids remained roughly constant after the fourth month. Lowest figures were obtained during lactation.—C. Warner.

FRAZIER, E. I. (with STUTES, A. L.) **The urinary excretion of tryptophan by human subjects on controlled diets varying in levels and sources of protein.** *J. Nutrition*, 1954, **53**, 115-127. [Dept. Home Econ., Agric. Exp. Stat., Alabama Polytech. Inst., Auburn.]

Twelve women aged 19 to 24 given a diet containing 9.8 g. N and 885 mg. tryptophan daily excreted about 30 mg. tryptophan daily in the urine, about 10 mg. being "free". With diets low in nicotinic acid, with 7.1 to 8.4 g. N and 521 to 616 mg. tryptophan, the amount of tryptophan

N.A. and R., January 1955

excreted was slightly less, though "free" tryptophan excretion was unchanged. There was no apparent relation between the amount of tryptophan excreted and the source or amount of dietary N, bodyweight, surface area, basal energy intake or urine volume. It is concluded that there was selective re-absorption of tryptophan from the glomerular filtrate by the tubules.—C. Warner.

LANG, K. Über Phenylpyruvische Oligophrenie. [Phenylpyruvic oligophrenia.] *Ztschr. Kinderheilk.*, 1954, 75, 132-139. [Kinderklin., Univ. Bonn.]

Two sisters with phenylpyruvic oligophrenia are described in detail. Their intelligence quotients (Binet) were at 11 years, 3 and at 7 years, 62. This metabolic abnormality behaves as a Mendelian recessive. It is characterised by an enzyme block which prevents the conversion of *l*-phenylalanine from food to *l*-tyrosine, so that *l*-tyrosine becomes an essential amino-acid. Phenylalanine accumulates in the blood, reaches an abnormally high level in cerebrospinal fluid and is deaminated in the kidney and excreted as phenylpyruvic acid. It is not known whether some other toxic product, such as phenylacetic acid, or lack of tyrosine is responsible for the mental deterioration and finally, idiocy. The lack of tyrosine causes abnormally fair skin and light hair. Administration of tyrosine, about half the daily requirement, *i.e.*, 1.0 to 1.5 g., improved the younger but not the older child. Glutamic acid has been reported helpful. No benefit from ascorbic acid or vitamin B₁ was seen.—I. Leitch.

NASSET, E. S. and GATEWOOD, V. H. Nitrogen balance and hemoglobin of adult rats fed amino acid diets low in *L*- and *D*-histidine. *J. Nutrition*, 1954, 53, 163-176. [Dept. Physiol., Sch. Med. Dent., Univ. Rochester, N.Y.]

Adult rats were fed for 2 weeks on a diet containing 9.6 per cent. whole egg protein and then received successively by stomach tube an N-free diet for 1 week, an amino-acid diet containing about half the total N required for maintenance for 1 week, and a complete amino-acid diet with twice this amount of N for 1 week. This 5-week cycle of feeding was repeated for 25 weeks. N balance and Hb were studied with different proportions of histidine in the amino-acid diet.

Reduction of histidine adversely affected the N balance. A positive N balance was obtained with one-fifth of the histidine present in the complete amino-acid mixture, but Hb values were reduced at that level and by as much as 20 per cent. at lower levels. Substitution of *D*- for *L*-histidine exerted no obvious effect on N balance or Hb concentration.—A. Hepburn.

782

EGGERT, R. G., WILLIAMS, H. H., SHEFFY, B. E., SPRAGUE, E. G., LOOSLI, J. K. and MAYNARD, L. A. The quantitative leucine requirement of the suckling pig. *J. Nutrition*, 1954, 53, 177-185. [Dept. Animal Husb., Cornell Univ., Ithaca, N.Y.]

Groups of 2-day-old suckling pigs were fed on a simulated milk diet lacking leucine but containing N as ammonium citrate, casein and amino-acids equivalent to 25 per cent. protein on an air-dry basis. Growth and feed efficiency were studied with *L*-leucine added at different levels in one experiment; in another carcass storage of protein, fat and ash was also estimated.

The *L*-leucine requirement was estimated to be between 1.00 and 1.25 per cent. of the diet, or not more than 5 per cent. of the dietary protein.

A. Hepburn.

HARPER, A. E., BENTON, D. A., WINJE, M. E. and ELVEHJEM, C. A. Leucine-isoleucine antagonism in the rat. *Arch. Biochem. Biophys.*, 1954, 51, 523-524. [Dept. Biochem., Coll. Agric., Univ. Wisconsin, Madison.]

Rats fed on diets containing 9 per cent. casein supplemented with *L*-leucine grew less well than those without leucine. The inhibition of growth produced by 1 per cent. *L*-leucine in the diet was completely prevented by adding 0.5 per cent. *D*-isoleucine, but not by any other amino-acid tested. The inhibition due to 3 per cent. leucine was almost

prevented by 1.7 per cent. isoleucine, but that concentration of isoleucine was itself slightly inhibitory.

GRAU, C. R. and STEELE, R. Phenylalanine and tyrosine utilization in normal and phenylalanine-deficient young mice. *J. Nutrition*, 1954, 53, 59-71. [Dept. Biol., Brookhaven Nat. Lab., Upton, N.Y.]

Mice were fed on amino-acid diets containing 0.7 per cent. L-tyrosine and either 0.1 or 0.7 per cent. L-phenylalanine for 5 to 14 days. Tyrosine or phenylalanine uniformly labelled with ^{14}C was then added to the diet and expired CO_2 was collected at intervals for 30 min., after which the animals were killed and the activity of the tyrosine and the phenylalanine of the liver proteins was estimated.

Animals fed on the phenylalanine-deficient diet absorbed less phenylalanine and oxidised less of that absorbed to liver protein tyrosine and to CO_2 than did normal animals; the deficient animals also absorbed less tyrosine and oxidised less of that absorbed to CO_2 , though incorporation into liver protein tyrosine was unimpaired; none was incorporated into liver phenylalanine.—C. Warner.

BAYETTA, L. A., BERNICK, S., GEIGER, E. and BERGREN, W. The effect of tryptophane deficiency on the jaws of rats. *J. Dent. Res.*, 1954, 33, 309-315. [Dept. Biochem., Sch. Dent., Univ. S. California, Los Angeles.]

Forty 21-day-old weanling rats were maintained on a standard ration for 1 week, and were then divided into 3 groups. The controls received a complete diet for 7 weeks, a second group received a tryptophan-deficient diet for 7 weeks, and a third group received the tryptophan-deficient diet for 3 weeks and the complete diet for 4 weeks. Representatives from each group were killed at 3 and at 7 weeks. The tryptophan-deficient diet contained an acid hydrolysate of casein as its source of N, and for the control diet 0.75 per cent. tryptophan was added.

The control rats made normal weight gains, but the tryptophan-deficient group lost weight; the repleted group made up this loss, but did not attain the weight of the control group by 7 weeks. The deficient rats developed alopecia and cataracts. Endochondral and periosteal bone formation was inhibited. At 3 weeks the femurs and alveolar processes of the alveolar teeth were affected; at 7 weeks, the dentine of the incisor teeth was imperfectly calcified, and the femurs showed marked osteoporosis. Such lesions were reversible on repletion with tryptophan.—W. A. Greig.

787

HARPER, A. E., BENTON, D. A., WINJE, M. E. and ELVEHJEM, C. A. "Antilipotropic" effect of methionine in rats fed threonine-deficient diets containing choline. *J. Biol. Chem.*, 1954, 209, 159-163. [Dept. Biochem., Coll. Agric., Univ. Wisconsin, Madison.]

Rats were fed to appetite on diets containing 9 per cent. casein, sucrose, fats, salts and vitamins, including choline, and the effects of adding combinations of methionine, tryptophan and threonine on the growth rate and liver fat content were studied for 2 weeks.

Tryptophan slightly increased growth rate, but had no effect on liver fat. Methionine alone or with tryptophan increased growth rate and considerably increased liver fat; little difference was noted between the effects of 0.1 and 0.6 per cent. methionine. Threonine gave an increased growth rate, especially in the presence of both methionine and tryptophan, and a decrease in liver fat content, slight in the absence of methionine, pronounced in its presence, always bringing the fat content below 16 per cent. of the dry weight.

It is suggested that when the primary deficiency of the diet in S-containing amino-acids is remedied, the secondary deficiencies of first threonine and then tryptophan become evident; the addition of methionine to the diet precipitates a threonine deficiency which causes liver fat to accumulate. When paired feeding was used, the food intake of animals fed on the basal diet supplemented with methionine and tryptophan being limited to that of those on the diet supplemented with tryptophan alone, no increase in liver fat was noted, presumably because the threonine did not become sufficiently low.—C. Warner.

EDWARDS, L. J. The absorption of methionine by the skin of the guinea pig. *Biochem. J.*, 1954, 57, 542-547. [Dept. Phys., Beecham Research Laboratories, Ltd., Brockham Park, Betchworth, Surrey.]

DL- ^{35}S -methionine was rubbed into the skin of guinea-pigs during 4 weeks, and the incorporation

N.A. and R., January 1955

of the ^{35}S into the protein of the growing hair was studied. With doses of 34 to 441 μg . methionine, about 1 per cent. of the ^{35}S was incorporated into the hair, mainly as cystine. When similar amounts of methionine were given in food about 2.5 times as much ^{35}S was incorporated in the hair, but since a large amount of the topically applied methionine was not absorbed and was washed off the subsequent hair clippings, and since the relative radio-activities of the liver, spleen and heart were similar in both groups, it appeared that the mechanism of utilisation of methionine was similar whether the amino-acid was eaten or absorbed through the skin. Intramuscular injection of methionine gave higher incorporation, about 5 per cent. of the ^{35}S being recovered from the hair after low doses, though higher doses gave relatively lower recoveries.—C. Warner.

DAVIES, D. F., WOLFE, K. M. and PERRY, H. M. (Jr.) Studies on primary amines. 2. Their natural occurrence in urine of normotensive and hypertensive subjects. *J. Lab. Clin. Med.*, 1954, 43, 620-632. [Dept. Int. Med., Sch. Med., Washington Univ., St. Louis, Mo.]

Methods were described in Abst. 55, Vol. 24.

Samples of urine were from 36 subjects, 12 normal, 20 with arterial hypertension and 4 with other disorders. As many as 8 amine spots were separated on paper chromatograms of single 24-hr. specimens of urine. The amines grouped themselves around 10 R_f peaks. There was no evidence that the number of amines excreted by patients with hypertension differed from the number excreted by normal subjects; many more data would be required for a study of the difference in frequency of occurrence of particular amines.

796

BARRY, J. M. Use of glutamine by the mammary gland for the synthesis of casein. *Nature*, 1954, 174, 315-316. [Dept. Agric., Univ. Oxford.]

1- ^{14}C -DL-glutamine was injected intravenously into a lactating goat and samples of blood and milk were taken at intervals up to 12 hr. Free glutamine in plasma had a specific activity many times that of free and plasma protein glutamic acid. After 3 hr. the specific activity of free glutamine in plasma decreased; free and combined glutamic acid remained about the same.

The acid hydrolysate of milk casein contained glutamic acid and the enzymic hydrolysate from the action of pancreas suspension contained in

addition glutamine. The specific activity of casein glutamine after 3 hr. was slightly higher than that of the free glutamine in plasma but that of casein glutamic acid was much lower. This suggested that free plasma glutamine was the main source of the glutamine residues in casein, which was confirmed by the injection of (1^{14}C :amide- 15N) DL-glutamine, when the ratio μC . per m. mol. carbon:atoms per cent. excess 15N in the glutamine of casein from milk after 1.5 hr. was approximately the same as in that injected. Glutamine did not lose its amide N and so apparently did not form intermediate γ -glutamyl peptides in the synthesis of casein.—A. Hepburn.

797

TANK, G. W. and HERRIN, R. C. **Effect of protein and amino acids upon renal function in the dog.** *Amer. J. Physiol.*, 1954, 178, 165-167. [Dept. Physiol., Med. Sch., Univ. Wisconsin, Madison.]

The post-absorptive creatinine clearances of 3 dogs were 85 to 90 ml. when the diet consisted of pork heart alone, but 56 to 72 ml. when the diet consisted of maize, salts and vitamins with 5 to 70 per cent. casein. No protein was found in the urine of any of the animals. Other dogs tested did not show these differences.

Intravenous infusion of alanine and, in 2 and sometimes a third of 5 dogs, of valine, increased the clearance of creatinine and of p -aminohippurate. Alanine usually decreased and valine usually increased the filtration fraction.—C. Warner.

798

SCHMIDT-NIELSEN, B. **Excretion of endogenous and exogenous creatinine and of mannitol in the kangaroo rat.** *Amer. J. Physiol.*, 1954, 178, 177-181. [Kettering Lab., Univ. Cincinnati, Ohio.]

Kangaroo rats, *Dipodomys merriami*, received a high-protein diet of soya bean meal and lettuce or a low-protein diet of barley, carrots and lettuce. Clearances of creatinine, mannitol and inulin were

studied by methods to be described (Schmidt-Nielsen, *Amer. J. Physiol.*, in the press).

The ratio of endogenous creatinine clearance: inulin clearance lay between 0.84 and 1.46, with only one figure below unity, and is thus comparable to the ratio reported in man (Hare *et al.*, *Federation Proc.*, 1949, 8, 67). After infusion of creatinine the creatinine: inulin clearance ratios indicated active secretion of creatinine by the renal tubules. The mean mannitol: inulin clearance ratio was 0.91, closely agreeing with figures for man and dog.

It is considered that endogenous as well as exogenous creatinine is secreted by the tubules in this species, but that secretion at low plasma concentrations becomes significant only when the filtration rate is low, so that at normal filtration rates the endogenous creatinine clearance is a measure of the glomerular filtration rate.—D. Daneman.

799

WILSON, D., BEYER, A., BISHOP, C. and TALBOTT, J. H. **Urinary uric acid excretion after the ingestion of isotopic yeast nucleic acid in the normal and gouty human.** *J. Biol. Chem.*, 1954, 209, 227-232. [Chronic Dis. Res. Inst., Univ. Buffalo, N.Y.]

About 1 g. yeast nucleic acid labelled with 15N was swallowed in gelatine capsules by 2 normal young men and a man of 65 with non-tophaceous gout. The rates of excretion of 15N in uric acid were similar in all; 47 to 73 per cent. of the ingested purine N was excreted as uric acid, but pyrimidine N was almost completely excreted as urea and ammonia, if conversion of purine to these products was neglected.

It is concluded that the purines of nucleic acid were rapidly converted to uric acid, or possibly to some precursor whose turnover rate was similar to that of uric acid, and that normal and gouty subjects did not differ significantly in their ability to do this.—C. Warner.

JOHNSON, W. A., FREEMAN, S. and MEYER, K. A. **The disappearance of intravenously injected emulsified fat from the circulation of patients and animals.** *J. Lab. Clin. Med.*, 1952, **39**, 414-419. [Dept. Exp. Med., Northwestern Univ. Med. Sch., Chicago, Ill.]

A preparation containing 10 per cent. olive oil in 5 per cent. glucose solution emulsified with 1 per cent. of a lecithin fraction was administered parenterally to human subjects at 1 g. fat per kg. bodyweight and to dogs at 0.5 g. fat per kg. bodyweight. The human subjects included patients with minor complaints to be treated by operation and others suffering from hyperthyroidism, liver cirrhosis and renal insufficiency; dogs were studied after bilateral ligation of the ureter or Eck fistula formation and in diabetes produced by alloxan. The emulsion was injected into the human subjects over 1 or 2 hr. and into dogs over 1 hr. Serum samples were analysed for total fatty acids, cholesterol and lipid P before, during and at intervals after injection of the fat emulsion.

In the human subjects 75 per cent. of the injected fat was removed from the blood by the end of the injection; a further 8 hr. was required to remove the remainder. Patients with glomerular nephritis and dogs with bilateral ureteral ligations removed the fat more slowly from the circulation than did normal groups. Cirrhotic patients and dogs with Eck fistulae showed less elevated blood fat values than corresponding controls. Removal of injected fat was slower in dogs with uncontrolled diabetes than in similar animals treated with insulin.—G. A. Garton.

LEWIS, G. T. and PARTIN, H. C. **Fecal fat on an essentially fat-free diet.** *J. Lab. Clin. Med.*, 1954, **44**, 91-93. [Med. Res. Found. Dade County, Miami, Fla.]

Three patients in hospital were given a diet containing daily not more than 25 mg. fatty acids. Faeces were collected daily (from one patient for 2 months) and analysed for total N and total ether-soluble material.

The average daily excretion of ether-soluble lipid was about 2 g. The faecal fat excreted bore no relation to the amount of N excreted. It is considered that the lipid is of endogenous origin, representing excretion by the intestinal mucosa.

G. A. Garton.

805

MAGEE, D. F. **Nature of the decrease in fecal fat resulting from the feeding of protein.** *Amer. J. Physiol.*, 1954, **177**, 285-286. [Dept. Pharmacol., Sch. Med., Univ. Washington, Seattle.]

Groups of rats and dogs were fed on diets rich in protein (gelatine or casein) or on high-carbohydrate diets of similar energy value. Faecal fat was estimated. After 21 days the rats were killed and the lipase activity of dried pancreas was estimated by the method of Archibald (Abst. 3854, Vol. 16).

Faecal fat excretion was less on the high-protein than on the high-carbohydrate diets. The different diets did not produce any great difference in the pancreatic lipase activity of the rats.

Influence of kind and quantity of fat on food and fluid consumption and urine production. 4. Influence of supplementation with raw skim milk, linoleic acid or both on growth. 5. Influence of supplementation with raw skim milk, linoleic acid or both on food and fluid consumption and urine production. *Brit. J. Nutrition*, 1954, **8**, 281-285; 285-289; 290-296; 296-301; 302-306. [Dept. Biochem., Polytech. Inst., Copenhagen.]

1. Weanling male rats were fed to appetite for 14 weeks on diets containing 7 per cent. lard or hydrogenated peanut oil or on a fat-free diet of the same basal composition. They drank water, raw skimmed milk or whey. Food and liquid intakes and urine production were measured and the animals were weighed weekly.

The rats grew significantly better on the diet containing 7 per cent. lard than on hydrogenated peanut oil, irrespective of what they drank. Growth was better, whichever fat was given, when the rats drank raw skimmed milk instead of water. Animals on the fat-free diet grew at the same rate as those on the diet containing hydrogenated peanut oil. Water consumption and urine production were greater when the diet with peanut oil or the fat-free diet was given in place of that with lard.

2. Groups of female weanling rats were given to appetite diets containing 7 per cent. of lard, peanut oil, coconut oil, hydrogenated peanut oil or hydrogenated whale oil. In some experiments the amount of fat in the diet was greater. The animals were weighed weekly for 16 weeks.

Rats grew equally fast on diets containing 7 per cent. lard, peanut oil or coconut oil; growth on hydrogenated fats was considerably slower.

Growth was little affected when the lard content of the diet was increased to 14 or 28 per cent., though similar increases in the dietary content of hydrogenated peanut oil reduced growth considerably. The growth of animals given 28 per cent. hydrogenated peanut oil and 20 per cent. casein was inferior to that of rats on a fat-free diet containing the same amount of casein.

3. This paper reports the food and fluid consumption and the urine output, during the last 13 weeks, of the animals described in the preceding abstract. Water intake was greater and urine output was less on diets containing hydrogenated fat and on fat-free diets than on diets containing lard, peanut oil or coconut oil. Animals fed on the hydrogenated fat or the fat-free diet had the greatest daily energy intake per unit of surface area; they had classical signs of essential fatty acid deficiency, including scaly tails and dry and scaly skin.

4. Weanling female rats, in 24 groups each of 6 animals, were reared for 18 weeks on diets containing 7 or 28 per cent. of lard, peanut oil or hydrogenated peanut oil, with or without linoleic acid, 150 mg. per animal weekly, and raw skimmed milk to drink.

Growth was faster when the lard or peanut oil was raised from 7 to 28 per cent., but slower when the higher level of hydrogenated peanut oil was given. Raw skimmed milk caused significantly faster growth than water in animals given the diets containing 7 or 28 per cent. hydrogenated peanut oil. When these diets were supplemented with linoleic acid growth was faster than that of animals which received the unsupplemented diet with water to drink. The growth-depressing effect of hydrogenated peanut oil was overcome to about the same extent by skimmed milk as by linoleic acid; the effect was most pronounced with 7 per cent. dietary fat. No explanation is offered.

5. The rats and diets used were those described in the preceding abstract; food and fluid intake and urine output were measured during 18 weeks. The ratio of total energy intake (less energy for water evaporation) to average daily weight gain was very high in rats given hydrogenated peanut oil; it was less when raw skimmed milk was given in place of water or when linoleic acid was added to the diet. The faster growth of animals given peanut oil or lard was not due to greater energy intake.—G. A. Garton.

SIEDLER, A. J. and SCHWEIGERT, B. S. **Effect of the level of animal fat in the diet on the maintenance, reproduction and lactation performance of dogs.** *J. Nutrition*, 1954, **53**, 187-194. [Div. Biochem. Nutrit., American Meat Inst. Found., Chicago, Ill.]

Groups of Cocker Spaniel bitches were fed on a basal diet "of ingredients commonly used in dry meals" with or without the addition of 4 or 8 per cent. rendered pork fat containing anti-oxidant or 18 per cent. of sucrose, at the expense of the basal ration. The animals in each group were bred to one of 2 dogs for the first litter and to the other dog for the second litter. The food intakes and weight gains of the bitches and their litters, the number of pups born, the number alive 24 hr. after birth and the number weaned were recorded.

Before breeding, the addition of 4 or 8 per cent. fat or 18 per cent. sucrose increased the efficiency of the diet for maintenance. The reproductive performance of the bitches given the diet containing 4 per cent. fat was better than that of the bitches fed on the basal diet. The reproductive capacity of those receiving 8 per cent. fat or 18 per cent. sucrose was poor. The average weight gain of pups from the bitches which had received 4 per cent. fat was greater than that of any other group.

MEAD, J. F. and FILLERUP, D. L. **Plasma lipids in fat deficiency.** *Proc. Soc. Exp. Biol. Med.*, 1954, **86**, 449-451. [Atomic Energy Project, Sch. Med., Univ. California, Los Angeles.]

Plasma was obtained from 26 male rats fed on a normal diet and from 16 male rats fed for 22 weeks on a fat-deficient diet; 18 of the animals fed on the normal diet were fasted for 12 to 20 hr. before sampling. Plasma lipids were extracted and the components were estimated by chromatography.

Total plasma lipids in fat-deficient rats were considerably less than in rats fed on the adequate diet, whether or not the latter had been starved. In fat deficiency the several classes of plasma lipids, triglycerides, sterols and sterol esters, expressed as percentages of the total, were reduced to about the same extent; the phospholipid fraction showed a relative increase.—G. A. Garton.

FRIEDMAN, M., ROSENMAN, R. H. and BYERS, S. O. **The role of exogenous lipids in the hyperlipemia and hypercholesteremia of nephrotic rats.** *J. Clin. Invest.*, 1954, **33**, 1103-1105. [Harold Brunn Inst., Mount Zion Hosp., San Francisco, Calif.]

Nephrosis was induced in rats by intravenous injection of 0.5 ml. rabbit anti-rat kidney serum on each of 2 successive days. Groups of these animals were then fed on a normal diet, a diet devoid of fats and sterols or the normal diet supplemented with 2 per cent. cholesterol and 1 per cent. cholic acid. Blood was obtained 4 and 6 days after the last injection of immune serum for estimation of total plasma cholesterol and total plasma lipids.

N.A. and R., January 1955

The increased values for total lipids and cholesterol found in the nephrotic rats on normal diet were found also in animals on the fat-free ration; it is suggested that this is due to a diminished rate of elimination from the plasma of lipids of endogenous origin. A greater retention of cholesterol in the plasma was observed in the nephrotic rats on the diet supplemented with cholesterol and cholate.—G. A. Garton.

810

ASADA, S. **Histochemical studies on the intravenously infused fat emulsion.** *Acta Scholae med. Univ. Kioto*, 1954, **31**, 171-192. [2. Surg. Div., Fac. Med., Univ. Kyoto.]

A stable fat emulsion containing 10 to 30 per cent. of cod liver oil and with a lipid ratio of neutral fat 85.5, fatty acid 7.9, lecithin 6.4 and other lipids 0.2 per cent. was administered intravenously to cats, mice and rabbits at 0.5 g. fat (3.3 ml. emulsion) per kg. bodyweight. Animals were killed at intervals after infusion and sections of lung, liver, spleen and kidney were examined for lipids with appropriate stains.

Fat embolism was not seen in any of the species; the fat globules were removed from the bloodstream about 30 min. after infusion. The fat globules in the lung were ingested by phagocytes, in the liver by Kupffer cells and in the spleen by reticulo-endothelial cells. No fat globule was seen in kidney or bile duct epithelium. Several hours after infusion there was extensive leucocytosis; the leucocytes ingested the infused fat globules.

When large quantities of the fat emulsion were administered by mouth or when the emulsion was administered to starved animals the fat in the phagocytes of the organs studied was histologically similar to that observed when standard amounts were administered intravenously. In the cat the infused fat was removed from the circulation more quickly than in the mouse and in the rabbit. When the fat emulsion was infused into rabbits daily for several weeks there was no abnormality except for a small deposit of fat in the reticulo-endothelial cells of the liver and spleen; when methionine was injected into rabbits simultaneously with the fat emulsion there was no accumulation of fat in these reticulo-endothelial cells.

It is concluded that the emulsion is suitable for human clinical use. In a supplement to the paper it is stated that when the emulsion was infused into human subjects before lobectomy or laparotomy no abnormality occurred and fat disposal was similar to that in the animals studied.

BECKER, G. H. and GROSSMAN, M. I. (with SMITH, J. R., TAYLOR, R. D., HOLLERMAN, W. A. and DECREASE, W. M.) **Studies on the thermo-**

Vol. 25, No. 1

genic response to intravenous fat emulsions. *J. Lab. Clin. Med.*, 1954, **43**, 752-758. [U.S. Army Med. Nutrit. Lab., Denver, Colo.]

Fat emulsions were tested by the Standard U.S.P. XIII pyrogen test with rabbits, but their effect was estimated from the highest rise above the control temperature in the 3 hr. after administration.

Reduction of the free fatty acid content of emulsions by treating the maize oil with alumina, ageing them or adding heparin did not affect the response. Autoclaving the emulsion resulted in a higher mean response, though the difference was not statistically significant. Peroxide after autoclaving was almost absent and is thus eliminated as a cause of the fever reaction. With emulsions containing large particles as a result of prolonged shaking there was some fat trapping and several rabbits died with signs of pulmonary embolism, but particle size could not be clearly correlated with fever response. The cause of the response remains obscure.—D. Duncan.

BEAUFALLET, M. and MAY, P. **Recherches concernant le rôle physiologique des acides gras polyéniques. 1. Teneur en ces constituants des phosphatides des divers parenchymes chez le jeune rat soumis à un régime normal ou lipidoprive. [Physiological role of polyene fatty acids. 1. Content of these substances in the phosphatides of the different parenchymatous tissues of the young rat normally fed or deprived of fat.]** *Rev. canad. Biol.*, 1953, **12**, 6-18. [Lab. Physiol. Gén., Sorbonne.] English summary.

Rats, the progeny of mothers fed on a complete or a fat-free diet, were maintained on the fat-free diet, consisting of, per cent., fat-free casein 18, glucose 78, and salts 4, with adequate vitamins. The offspring of the mothers deprived of fat had at 3 weeks old only about half the bodyweight of the offspring of the mothers not deprived, and their survival time was inversely related to the number of young in the litter, but never exceeded 60 days. Young rats thus reared on the fat-free diet for 50 days were then killed, and the brain, liver, kidneys, heart and carcass were extracted with alcohol and light petroleum. Phosphoaminolipids were separated by precipitation with acetone and subjected to saponification and isomerisation, which brought about conjugation of the double bonds. They were examined spectrophotometrically, since the dienes, trienes, tetraenes, pentaenes and hexaenes, which are contained in the phosphoaminolipids of the normal young rat, have characteristic maxima of absorption.

In the normal rats all the polyene acids investigated were present in the tissues examined, the

amount of hexaene acid being particularly high in the brain.

In the rats having the fat-free diet, the content of polyenes in the brain was little changed except for the hexaene, of which the amount was about halved. In the heart the amount of triene tended to be increased, of tetraene to be unchanged, and of the remainder to be much decreased. In the other tissues the amount of triene was unchanged and of the remainder was greatly reduced.

SCRIBANTE, P. and FAVARGER, P. Étude de la digestibilité de l'acide stearique et de ses esters glycériques chez le rat. [Digestibility of stearic acid and its glyceryl esters by the rat.] *Helv. physiol. pharm. Acta*, 1954, 12, 74-89. [Inst. Chim. Physiol., Univ. Geneva.]

The true and apparent digestibilities of the saturated triglycerides tristearin, tripalmitin, trimyristin and trilaurin and of stearic acid and some of its glyceryl esters were studied with rats. The digestibility of stearic acid depended on the chemical form in which it was ingested; the most readily digestible form found was the monostearate. The excretion of endogenous fat was not constant and increased with a decrease in the coefficient of digestibility of the food fat.—G. A. Garton.

RAPPAPORT, A. M., BOROWY, Z. J., LOUGHEED, W. M. and LOTTO, W. N. Subdivision of hexagonal liver lobules into a structural and functional unit. Role in hepatic physiology and pathology. *Anat. Rec.*, 1954, 119, 11-33. [Dept. Physiol., Univ. Toronto.]

A new concept of the smallest structural and functional unit of the liver is described. The unit is not the hexagonal field which is seen histologically, but occupies adjacent fields and extends from one central vein to the next. Difficulties in correlating the distribution of hepatic lesions with the arrangement of hexagonal fields may be explained by reference to this concept of the circulatory pattern.—D. Duncan.

815

HARTROFT, W. S. The trabecular anatomy of late stages of experimental dietary cirrhosis. Its pathogenesis in terms of Rappaport's structural unit. *Anat. Rec.*, 1954, 119, 71-93. [Banting and Best Dept. Med. Res., Univ. Toronto.]

The livers of over 350 rats on several diets low in lipotropic substances were examined. Representative animals were perfused through the left ventricle with Indian ink to show up the circulatory pattern. It was shown that the distribution of fibrous tissue in both early and late cirrhosis is non-portal in a functional sense although geographically

periportal. It can be best comprehended by reference to Rappaport's concept (see preceding Abst.) of the functional structural unit of the liver.

CLÉMENT, G., CLÉMENT, J. and LE BRETON, E. Recherches sur les déséquilibres entre les constituants lipidiques des structures cellulaires au cours de l'installation de l'hépatome expérimental du rat. 2. Étude du foie de rat ayant ingéré un régime équilibré additionné de cholestérol. [Disequilibrium in the lipid constituents of cell structures during the establishment of experimental hepatoma in the rat. 2. Study of the liver of the rat on a balanced diet with additional cholesterol.] *Arch. Sci. physiol.*, 1954, 8, 259-277. [Dept. Physiol., Inst. Recherches Cancer Gustave Roussy, C.N.R.S., Univ. Paris.]

Male rats were fed for from 15 to 24 months on an adequate diet containing 5 per cent. amorphous cholesterol. Their livers were examined histologically at the end of the experiment and also analysed for total fat. The microsomes, mitochondria and other cell fractions were separated in 30 per cent. sucrose solution and analysed for glycerides, cholesterol esters, phospholipins and unsaponifiable matter.

The fatty livers contained "free" lipid which consisted mainly of cholesterol esters, glycerides and a fraction of the unsaponifiable matter. An increase of hepatic parenchyma occurred.

818

HARPER, A. E., BENTON, D. A., WINJE, M. E. and ELVEHJEM, C. A. On the lipotropic action of protein. *J. Biol. Chem.*, 1954, 209, 171-177. [Dept. Biochem., Coll. Agric., Univ. Wisconsin, Madison.]

Rats were fed for 2 weeks after weaning on low-protein diets supplemented with different amounts of choline, methionine and protein. They were then killed and total liver lipids were estimated by ether extraction of the dried and ground tissue.

Neither choline nor methionine, in amounts satisfactory for normal growth, prevented the accumulation of some excess fat in the liver. Liver fat values were reduced to what is considered the normal range only when extra protein or threonine was added to the basal diet.

It is concluded that dietary protein exerts two distinct effects on deposition of liver fat; first, the well-established effect of methionine in sparing choline, and second, the provision of certain amino-acids (e.g., threonine), deficiencies of which cause fat to accumulate in the liver.—G. A. Garton.

819

HARPER, A. E., BENTON, D. A., WINJE, M. E., MONSON, W. J. and ELVEHJEM, C. A. **Effect of threonine on fat deposition in the livers of mature rats.** *J. Biol. Chem.*, 1954, **209**, 165-170. [Dept. Biochem., Coll. Agric., Univ. Wisconsin, Madison.]

Groups of rats were fed for several weeks on a basal diet consisting of sucrose 81.4, casein 9.0, maize oil 5.0, salts 4.0, methionine 0.3, tryptophan 0.1 and choline chloride 0.15 per cent. and adequate vitamin supplements; alterations in this diet were compensated by alterations in the amount of sucrose. Animals were killed at intervals for estimation of liver lipids and their cholesterol and P content.

The amount of liver fat in rats fed to appetite on the basal diet for 10 weeks after weaning decreased gradually as the animals matured and their protein requirement decreased. Fat accumulated in the livers of mature rats fed on the basal diet containing 5 per cent. protein, but fat deposition was less when supplementary threonine or glycine also was included in the diet.

G. A. Garton.

820

HARTMANN, F. and NICKEL, A. **Vergleichende Untersuchungen über die lipotrope Wirkung von Cholin und Methionin sowie einiger ihrer Verbindungen an der CCl₄-vergifteten Ratte.** [Comparative studies of the lipotropic action of choline and methionine and of some of their compounds on rats poisoned with carbon tetrachloride.] *Arch. exp. Pathol. Pharmacol.*, 1954, **222**, 518-522. [Med. Klin., Univ. Göttingen.]

Comparative estimations were made of the lipotropic effect of choline, methionine and 3 derivatives in lowering the content of total lipids and neutral fats in the liver of rats poisoned with CCl₄. All the substances tested had a lipotropic action,

but the best effect was given by a combination of choline and methionine, and by the choline salt of guanil urea sulphonic acid. The lipotropic effect of methionine and choline was enhanced in derivatives which increased the utilisation of CH₃-groups for phosphatide synthesis.—M. B. Richards.

821

BENDANDI, A. and MANFREDI, G. C. **Variazioni dei gruppi sulfidrilici epatici in corso di terapia lipotropa.** [Variations in sulphydryl groups in the liver in the course of lipotropic treatment.] *Arch. internat. Pharmacodyn.*, 1954, **98**, 152-160. [Ist. Clin. Med., Univ. Modena.]

Literature on the different behaviour of lipotropic agents on fatty liver characterised chemically by the presence of triglycerides and on cholesterol fatty liver is briefly discussed. Experiments were made on 135 male albino rats of weight between 150 and 200 g. Fatty liver was induced by subtotal removal of the liver; by giving CCl₄; by giving a diet with 40 per cent. fat of low iodine number and only 7 per cent. of milk protein for 16 days. The lipotropic substances tested were: methionine, 100 mg. daily by intramuscular injection; choline chloride, 25 mg. daily by the same route; inositol, 60 mg. daily by the same route; lipotropic substance from the pancreas, which was added to the high-fat, low-protein diet, or to a diet with 15 per cent. casein and 20 per cent. oil and given to rats from which part of the liver had been removed, or rats given CCl₄. At the end of the experiments the rats were killed by bleeding. SH groups in liver were estimated by the nitroprusside method of Fujita and Numata (*Abst. 25*, Vol. 9) in the modification of Leaf and Neuberger (*Abst. 2100*, Vol. 17).

Each of the lipotropic agents reduced liver fat. Choline and inositol had less effect on fat accumulating after removal of part of the liver; methionine was most and pancreatic extract least effective in CCl₄ poisoning. Each of the lipotropic agents increased SH groups in liver, which were greatly reduced in dietary fatty liver and below normal in CCl₄ poisoning. With and without lipotropic supplement, SH groups were well above normal in the stump of the liver.—I. Leitch.

WILGRAM, G. F., HARTROFT, W. S. and BEST, C. H. **Dietary choline and the maintenance of the cardiovascular system in rats.** *Brit. Med. J.*, 1954, ii, 1-5. [Banting and Best Dept. Med. Res., Univ. Toronto.]

In all, 421 rats, weighing initially from 70 to 120 g., were used, and experiments lasted for from 12 to 60 days. Five basal choline-deficient diets contained different amounts of protein and

methionine, and one containing 35 per cent. ethyl laurate was semi-liquid. The tissues of all rats were examined when they died or were killed.

The ethyl laurate diets produced cardiac necrosis, which was prevented by a choline supplement. Stainable fat droplets appeared in the heart muscle before necrosis developed. Several synthetic triglycerides, triacprolin, triacprilin, trilaurin, trimyristin and tripalmitin, also produced cardiac damage when given at 25 or 40 per cent. in choline-deficient diets. On a fat-free diet 2 of 13 choline-deficient rats developed cardiac necrosis and 4 succumbed to haemorrhagic kidney lesions, indicating that omission of fat reduced the severity of the deficiency. Beef fat and lard produced more severe changes than maize oil or coconut oil.

Cardiac lesions occurred in 25 rats in the absence of kidney damage, but never in the absence of fatty liver. It is suggested that lipotropic substances may be necessary not only for the liver, but also for the maintenance of normal cardiovascular and renal systems in rats.—D. Duncan.

A plasma lipid tolerance test for man has been developed. The level of blood lipids was studied before and 5 hr. after a meal containing about 70 g. each of fat, protein and carbohydrate.

In healthy subjects the difference between the pre- and post-prandial levels was less than 2 g. per cent.; in atherosclerotic patients it was 3 to 6 g. per cent., in arteriosclerotic diabetics 2 to 5 g. per cent., and in arteriosclerosis without diabetes 2.5 to 3 g. per cent. A normal rise in blood fat was observed in healthy obese subjects and in diabetics free from degenerative complications.

It is suggested that the method will be of use in studying the effect of therapeutic procedures in atherosclerotic and arteriosclerotic conditions.

GOLDBLOOM, A. A., EIBER, H. B. and BOYD, L. J. Clinical studies in blood lipid metabolism. 9. Effect of lipotropic agents on serum lipid partitions in fifty patients with generalized atherosclerosis: a three year study. *Amer. J. Digest. Dis.*, 1954, 21, 152-157. [Med. Serv., New York Med. Coll., Flower and Fifth Avenue Hosps., N.Y.]

A diet low in fat and cholesterol was taken for 36 months by 50 hospital patients with general atherosclerosis and chronic coronary artery disease; 25 of these patients took 9 to 12 capsules daily of a lipotropic preparation containing, per capsule, choline dihydrogen citrate 2.5 g., dl-methionine 1.0 g., inositol 0.75 g., vitamin B₁₂ 18 µg. and liver concentrate and desiccated liver 0.78 g. Serum cholesterol, phospholipins, total lipids and neutral fat were estimated at the beginning of the experiment and thereafter at intervals of 6 months.

Except for a slight fall in the serum cholesterol values of all patients, attributable to the nature of the diet, no significant difference was found in any of the other lipid fractions; no clinical liver damage was occasioned, as judged by liver function tests.—G. A. Garton.

830

REINIS, Z. and HRABÁNEJ, J. Lipoproteiny v krvi u experimentální atheromatosis. [Blood lipoproteins in experimental atheroma.] *Čas. Lék. čes.*, 1954, 93, 497-502. [4. Int. Clin.] Russian and English summaries.

Rabbits were given cholesterol for 12 months and blood cholesterol and lipoproteins were estimated regularly by electrophoresis. Both values rose steadily. Injection of horse serum into the rabbits prevented the cholesterol-lipoprotein complex from being formed, so that the excess of cholesterol accumulated in the blood but the lipoproteins did not increase. (From summary.)

FELCH, W. C., DOTTI, L. B., REISSNER, D. J. and KEATING, J. H. The time factor in atherosclerosis. *J. Lab. Clin. Med.*, 1954, 43, 914-917. [Dept. Med., St. Luke's Hosp., New York.]

Four groups each consisting of 6 rabbits were fed on a diet containing 6 g. cholesterol and 6 g. salad oil per head daily. The groups were killed after 5, 11, 18 and 25 days, before which blood samples were taken for estimation of total and ester cholesterol and lipid P. The aortas were examined for the presence of atherosclerotic lesions, which were found as early as 11 days.

Serum obtained from rabbits fed on the high-cholesterol diet was injected intravenously into normal animals. Traces of possible atherosclerotic lesions developed within 24 to 48 hr. Repeated daily injections of such serum into normal rabbits produced definite slight lesions after 4 and gross lesions after 30 injections.

It is suggested that a transient abnormality in serum lipids may lead in the end to clinical atherosclerosis.—G. A. Garton.

832

KRITCHEVSKY, D., MOYER, A. W., TESAR, W. C., LOGAN, J. B., BROWN, R. A., DAVIES, M. C. and COX, H. R. Effect of cholesterol vehicle in experimental atherosclerosis. *Amer. J. Physiol.*, 1954, 178, 30-32. [Viral and Rickettsial Res. Sect., Lederle Labs. Div., American Cyanamid Co., Pearl River, N.Y.]

Groups of rabbits were fed for 2 months on chow supplemented with 3 per cent. cholesterol, 3 per cent. cholesterol and 9 per cent. maize oil or 3 per cent. cholesterol and 9 per cent. hydrogenated vegetable oil. Total cholesterol and lipoproteins were estimated at the beginning and end of the experiment. The aortas were examined for atherosclerotic lesions and the livers were analysed for total non-saponifiable matter and cholesterol.

The atheromatous lesions were greatest in the groups given the cholesterol supplement alone or with hydrogenated vegetable oil; the lesions were less severe in animals given cholesterol with maize oil. The serum cholesterol and S₁ lipoproteins were increased to a greater extent on the diets containing both fat and cholesterol than on the diet with cholesterol only. Liver cholesterol and

total unsaponifiable matter were increased to the greatest extent on the diet containing maize oil and cholesterol, though the values found after cholesterol with hydrogenated vegetable oil were greater than those observed when the basal diet was supplemented with cholesterol only.

833

KRITCHEVSKY, D., MOYER, A. W., TESAR, W. C., LOGAN, J. B., BROWN, R. A. and RICHMOND, G. Squalene feeding in experimental atherosclerosis. *Circulation Res.*, 1954, 2, 340-343. [Lederle Labs. Div., American Cyanamid Co., Pearl River, N.Y.]

The role of endogenous cholesterol in the production of atherosclerosis was studied by giving squalene, said to be an immediate precursor of cholesterol, to rabbits. One group was given 3 per cent. squalene for 7 weeks, another for 14 weeks. A third group was given 3 per cent. cholesterol and a fourth 3 per cent. cholesterol and 3 per cent. squalene for 7 weeks. The supplements were given in maize oil. A fifth group of control rabbits had the same basal diet but no supplement.

At the beginning and end of the experiment serum was examined by ultracentrifuge for β -lipoproteins. All animals were killed at the end of the experiment; livers were weighed and analysed for total non-saponifiable material and cholesterol and aortas were inspected for atherosclerotic lesions.

Seven weeks of squalene feeding caused an increase in total non-saponifiable material in liver and 14 weeks of squalene produced also increases in liver cholesterol and serum lipoproteins, but these increases were small compared to those produced by cholesterol with or without squalene. The addition of squalene to the cholesterol supplement did not lessen the severity of the induced atherosclerosis, and squalene alone did not produce appreciably more atherosclerosis than was seen in the control group.—F. C. Aitken.

MOSES, C. Effect of oral inositol phosphatide on development of experimental atherosclerosis. *Geriatrics*, 1954, 9, 325-326. [Addison H. Gibson Lab., Univ. Pittsburgh, Pa.]

Administration by stomach tube of 100 ml. of a 2 per cent. solution of inositol phosphatide 3 times a week for 4, 8 or 12 weeks to male rabbits receiving a high-cholesterol diet did not decrease the incidence of atherosclerosis and had no effect on weight gain, serum cholesterol partition, cholesterol:lipid P ratio, urea N, total serum protein or haematocrit.—F. C. Aitken.

- ADLERSBERG, D., SCHAEFER, L. E. and WANG, C. I. Adrenal cortex, lipid metabolism and atherosclerosis: experimental studies in the rabbit. *Science*, 1954, 120, 319-320. [Dept. Med., Mount Sinai Hosp., New York 29.]

Groups of rabbits, fed on Purina chow, were treated with cortisone acetate, hydrocortisone acetate or corticotropin. Fractionation and estimation of plasma lipids revealed high total and ester cholesterol, phospholipins and neutral fat, especially the latter.

Other groups of rabbits, fed on high-cholesterol diets, were similarly treated with cortisone or hydrocortisone and showed an increase of all plasma lipid values greater than those observed when cholesterol alone was given; when corticosteroid treatment ceased the plasma lipid levels fell to those characteristic of high cholesterol intake alone. No significant additional increase of plasma lipid values was found when corticotropin was administered to cholesterol-fed rabbits.

- BALAGUER-VINTRÓ, J. La aterosclerosis inducida por el colesterol y sus mecanismos de inhibición. [Atherosclerosis induced by cholesterol, and inhibitory mechanisms.] *Rev. española Fisiol.*, 1954, 10, 1-8. [Esc. Cardioangiol., Univ. Barcelona.] English summary.

A study was made of atherosclerosis in chicks when 4 per cent. cholesterol was added to their diet for 12 weeks from 1 month old. The effects of methionine, inositol and KI were also studied.

The degree of atherosclerosis of the thoracic aorta was greatest in the group receiving cholesterol only. In general both frequency and intensity of the lesions were less in the groups receiving one of the other substances in addition to cholesterol, although in all groups at least one animal showed lesions of maximum intensity. There was an inverse relation between the intensity of the affection and the total blood cholesterol. In the control group blood cholesterol average was on the average 130 and in the cholesterol group 360 mg. per cent., but the KI group, in which the intensity of the lesions was least, had a blood cholesterol value of 615 mg. per cent.

- BAEDER, D. H., BECKFIELD, W. J. and SEIFTER, J. Effect of aluminium hydroxide gels on experimental hypercholesterolemia and atheroma-

tosis in chicks. *Proc. Soc. Exp. Biol. Med.*, 1954, 86, 326-329. [Wyeth Inst. Appl. Biochem., Univ. Pennsylvania, Philadelphia.]

Diets containing cholesterol and 3 per cent. of aluminium hydroxide gels were given to cockerels for 15 weeks; blood cholesterol was estimated at intervals and at the end of the experiment organs were removed, weighed and examined histologically. The aortas were graded according to the degree of atheromatosis.

Aluminium hydroxide gel did not prevent atheromatosis or raised blood cholesterol in these birds, a finding contrary to those of Rodbard *et al.* (*Circulation*, 1950, 2, 479) and Rodbard and Bolene-Williams (*Fed. Proc.*, 1952, 12, 118). Neither inanition nor paralysis resulted from these diets; the blood cholesterol value was proportional to the cholesterol intake. Some birds were given also cortisone acetate or boric acid, but neither influenced the development of arterial lesions.

- WILGRAM, G. F., HARTROFT, W. S. and BEST, C. H. Abnormal lipid in coronary arteries and aortic sclerosis in young rats fed a choline-deficient diet. *Science*, 1954, 119, 842-843. [Banting and Best Dept. Med. Res., Univ. Toronto.]

Groups of young male rats were fed for 4 weeks on a low-choline, high-fat diet; control animals received the same diet supplemented with 0.85 per cent. choline chloride. Before the end of the experiment half the animals on the low-choline diet died from acute haemorrhagic renal lesions.

At post-mortem no gross or microscopic abnormality of the cardiovascular system was found in the animals with choline supplements. In the choline-deficient animals, lipid deposits were found in the walls of coronary arteries and aortas; microscopically the aortic lesions consisted of intimal and medial deposits of lipid, often associated with pathological amounts of Ca salts in the media. Wherever fat was demonstrable histologically in the lining endothelial cells they were distended.—G. A. Garton.

- McGILL, H. C. and HOLMAN, R. L. Alteration in ground substance in experimental necrotizing endocarditis. *Arch. Pathol.*, 1954, 57, 431-438. [Dept. Pathol., Sch. Med., Louisiana State Univ., New Orleans.]

About 90 per cent. of dogs fed on a high-fat diet rich in butter and with renal insufficiency, produced experimentally by several methods, developed necrotic arterial and endocardial lesions. Renal insufficiency or high-fat diet alone produced no such lesion.

Necrotic lesions of the left auricular endocardium were found in 7 of 11 dogs. Early lesions were

N.A. and R., January 1955

associated with heavy deposits of acid mucopolysaccharide which disappeared as necrosis progressed. Much smaller quantities of similar material were found in auricular endocardium of apparently normal dogs and in those subjected to renal insufficiency only.—D. Duncan.

BEST, M. M., DUNCAN, C. H., VAN LOON, E. J. and WATHEN, J. D. Lowering of serum cholesterol by the administration of a plant sterol. *Circulation*, 1954, 10, 201-206. [Inst. Med. Res., Sch. Med., Univ. Louisville, Ky.]

Of 9 hospital patients in this study 2 had serum cholesterol values within the normal range and were without evidence of cardiovascular or renal disease, the other 7 had high blood cholesterol values and all suffered from some vascular or renal disorder. The patients, on unrestricted diet, were each given 5 to 6 g. β -sitosterol daily immediately before food, for from 13 to 29 weeks; 2 periods of placebo administration were included in the experimental regimen of each. Total serum cholesterol and lipid P were estimated weekly. The lipoproteins of 3 patients were examined in the analytical ultracentrifuge.

After administration of β -sitosterol a significant reduction of total serum cholesterol was accompanied by a lowering of the ratio of serum cholesterol to lipid P; no toxic or unpleasant side effect was found. The ultracentrifuge studies revealed a reduction in the "atherogenic" S₁ 10-100 classes of lipoproteins.

It is considered that β -sitosterol interferes with the absorption of cholesterol, both that of dietary origin and that excreted into the digestive tract.

BEHER, W. T. and ANTHONY, W. L. Effect of dihydrocholesterol and soy bean sterols on elevated tissue cholesterol. *Proc. Soc. Exp. Biol. Med.*, 1954, 86, 589-590. [Edsel B. Ford Inst. Med. Res., Henry Ford Hosp., Detroit, Mich.]

Mice received to appetite for 2 weeks a fat-free diet supplemented with 1 per cent. cholesterol and 0.5 per cent. cholic acid. They were then divided into 2 groups; the controls received the unsupplemented diet to appetite, and the others were fed on the same diet plus 2 per cent. dihydrocholesterol and 0.5 per cent. cholic acid. Groups of 7 or 8 mice were killed weekly for 4 weeks and

their liver cholesterol was estimated by the method of Beher and Anthony (Abst. 4850, Vol. 24).

Dihydrocholesterol did not increase the rate of mobilisation of liver cholesterol.

In further experiments rabbits were fed to appetite for 2 weeks on a diet of Rockland rabbit chow containing 1 per cent. cholesterol and 8 per cent. maize oil to raise their plasma cholesterol values. They were then divided into 2 groups; the control group was fed on the chow diet containing 8 per cent. maize oil and the other group received the same diet supplemented with 4 per cent. soya bean sterols. Plasma cholesterol values were estimated thereafter every few days.

The rate of fall of plasma cholesterol was not higher in the group receiving soya bean sterols than in the control group.—G. A. Garton.

844

SWELL, L., BOITER, T. A., FIELD, H. (Jr.) and TREADWELL, C. R. Esterification of soybean sterols *in vitro* and their influence on blood cholesterol level. *Proc. Soc. Exp. Biol. Med.*, 1954, 86, 295-298. [Veterans Admin. Centre, Martinsburg, W. Va.]

Rats in 6 groups of 8 animals were fed for 7, 14 or 21 days on diets without, or with 0.5, 1, 2, 3 or 4 per cent. soya bean sterols. The basal diet was composed of casein 20, starch 22, glucose 23, olive oil 25, salt mixture 5, Ruffex 2, cholesterol 2 and Na taurocholate 1 per cent., with adequate vitamin supplements; soya bean sterols were added at the expense of starch and glucose. Blood samples were taken for cholesterol analysis.

The presence of soya bean sterols in the diet inhibited the increase in blood cholesterol and the degree of inhibition increased as the amount of soya bean sterols increased.

In experiments *in vitro* it was demonstrated that pancreatic cholesterol esterase promoted the esterification of soya bean sterols, though it was slower than esterification of cholesterol.

It is concluded that, *in vivo*, soya bean sterols probably compete with cholesterol for the esterifying enzyme and so impair the absorption of cholesterol.—G. A. Garton.

LANDON, E. J. and GREENBERG, D. M. Endogenous cholesterol metabolism in the rat studied with C¹⁴-labeled acetate. *J. Biol. Chem.*, 1954, 209, 493-502. [Dept. Physiol. Chem., Sch. Med., Univ. California, Berkeley.]

Male rats fed on a diet free from cholesterol were injected intraperitoneally with CH₃¹⁴COONa three times at 4-hr. intervals. Some were killed 4 hr. after the last injection and others later. The radioactivity of tissue cholesterol was estimated.

Carrier cholesterol was added for serial estimations of serum radio-activity on a single rat.

Most of the metabolism of cholesterol was evidently confined to liver, intestine and adrenal, which had high rates of turnover, the turnover time of liver being about 40 hr. Skin contained a large quantity of Δ^7 -cholesterol, which may be rapidly exchangeable with cholesterol. With normal animals interruptions in the decline of specific activity occurred in serum, intestine and liver. Rats with a bile fistula or a ligated bile duct did not show this effect, which was caused by secretion of radio-active cholesterol from the bile into the intestine and its re-absorption. All the secretion of radio-active cholesterol into the bile occurred within 6 hr. of the acetate injection.

The radio-activity of cholesterol in the spleen, lung, testis, kidney and adrenal was highest 16 hr. after the last injection of acetate. As at this time significant amounts of radio-active non-steroid precursors were not available for cholesterol formation, the turnover of cholesterol was thought to occur primarily by exchange in the plasma. The turnover time of cholesterol in the adrenals was about the same as that in liver, which supports the theory that adrenal cholesterol is the precursor of steroid hormones.

Castration 72 hr. before injection of acetate resulted in a marked slowing of the turnover of cholesterol in liver and intestine. As its low specific activity excludes the testis as a major site of catabolism, this reduced turnover is apparently effected directly or indirectly by the male sex hormones.—A. Hepburn.

846

BIGGS, M. W., LEMMON, R. M. and PIERCE, F. T. (Jr.) Observations on Δ^7 -cholesterol metabolism in the rabbit. *Arch. Biochem. Biophys.*, 1954, **51**, 155-160. [Radiation Lab., Univ. California, Berkeley.]

Tritium-labelled Δ^7 -cholesterol dissolved in cottonseed oil was given by stomach tube to 2 rabbits in which blood fat had been increased by continuous feeding with cholesterol. Blood samples were taken after 1, 2, 3, 4, 6 and 10 days for estimation of free and total cholesterol and measurement of radio-activity. A third rabbit was similarly treated after having been given tritium-labelled cholesterol by stomach tube.

After administration of radio-active cholesterol, tritium-labelled sterol appeared in the free and total cholesterol pools of the serum in a manner which was qualitatively similar to that found after administration of labelled cholesterol. The conversion of Δ^7 -cholesterol to cholesterol was confirmed by isolation of tritium-labelled cholesterol from the livers of both the animals which had received Δ^7 -cholesterol.—G. A. Garton.

847

LEMMON, R. M., PIERCE, F. T. (Jr.), BIGGS, M. W., PARSONS, M. A. and KRITCHEVSKY, D. The effect of Δ^7 -cholesterol feeding on the cholesterol and lipoproteins of rabbit serum. *Arch. Biochem. Biophys.*, 1954, **51**, 161-169. [Radiation Lab., Univ. California, Berkeley.]

One group of rabbits was fed on a diet containing 1 per cent. cholesterol and Wesson oil, the second group received Δ^7 -cholesterol instead of cholesterol and the third group 1 per cent. of each. Blood samples were taken before these diets were begun and after 1 and 2 weeks for lipoprotein analysis and estimation of serum cholesterol.

The Δ^7 -cholesterol produced a rise in low-density serum lipoproteins and cholesterol which was qualitatively the same as that produced by cholesterol. The 2 sterols together had an additive effect on the levels of serum lipoproteins.

MÜLLER, F. Der Ketonkörperstoffwechsel im Hungerzustand und bei chronischer Unterernährung. [Ketone body metabolism in the fasting state and in chronic undernutrition.] *Ztschr. ges. exp. Med.*, 1954, **124**, 72-92. [Med. Klin., Univ. Greifswald.]

The aim was to investigate, with the help of metabolic test feeding, the course of fat combustion, ketogenesis and ketolysis in the fasting state and in chronic undernutrition. Preliminary experiments on healthy non-fasted dogs and human beings, given caproic acid, showed how actively and quickly fats take part in the combustion process, and contradicted the prevalent idea that fats are metabolically inert and burn with difficulty.

When dogs and human subjects were given injections of caproic acid after fasting, there was a striking delay in the fall of blood ketone values after the original rise. This delay could be most easily explained by inhibition of ketolysis. There was, moreover, especially in man, a considerable rise in blood ketone level. Ketogenesis in the liver was apparently not affected, since the high ketone peaks were reached in the same short time after injection as in the non-fasting subject. Inhibition of ketolysis after caproic acid was observed also in dystrophic dogs, although sufficient carbohydrate was provided by the diet. It is therefore concluded that the inhibition is not due to lack of carbohydrate, but is caused mainly by a fall in insulin production and deterioration of the metabolic turnover consequent on general cell damage. Both in complete starvation and in dystrophy the changes observed in fat metabolism were similar to those found in diabetes mellitus.

- CORNATZER, W. E. and GALLO, D. G. Effects of dietary aureomycin and sulfasuxidine on phosphorylation in the liver of rats. *Proc. Soc. Exp. Biol. Med.*, 1954, **86**, 15-18. [Med. Sch., Univ. N. Dakota, Grand Forks.]

Young rats weighing initially 100 to 110 g. received a basal low-protein, low-fat diet containing vitamin-free casein 5, dextrin 42, sucrose 42, Crisco 4, cod liver oil 1, salt mixture 4, and Ruffex 2 parts, with a vitamin supplement supplying vitamin B₁, riboflavin, pyridoxine, nicotinic acid, calcium pantothenate, inositol and *p*-aminobenzoic acid. Groups of rats received supplements of aureomycin, 25 mg. daily for 1, 2, 4 or 8 weeks, or

of sulphasuxidine, 5 per cent. for 5 or 7 weeks. At the end of these periods each rat received 2 to 4 μ C. ³²P intraperitoneally and was killed 6 hr. later for study of the liver P distribution.

Although aureomycin increased the growth and food consumption of the rats it had no significant effect on the quantity of liver lipids or on phospholipin or nucleoprotein formation. Sulphasuxidine inhibited growth and decreased food consumption, and the livers of these rats contained less lipid, but formation of phospholipin and nucleoprotein appeared to be increased.—D. Duncan.

Adult rats were fed on a stock diet alone or with sulphonic ion resin at 15, 10 or 5 per cent. Growth was restricted in animals receiving 15 per cent. resin and deaths occurred earlier in this group than others. Resin reduced absorption of Na and K and increased absorption of phosphate, but did not affect Ca or Mg. Animals receiving 10 per cent. resin grew and survived normally although the effective Na content of the diet was only 0.02 per cent.—R. Hill.

Experiments were made on normal subjects and on hospital patients with or without metabolic bone disease. All had a calculated Ca and P intake for 3 to 5 days before the test. Calcium gluconate was infused in NaCl solution for 3 hr., the total dose of Ca being about 10 mg. per kg. bodyweight or 600 mg. in all.

By the end of the Ca infusion a significant rise of serum P occurred in all control subjects and in those with osteoporosis and osteomalacia. The serum P level was not related to the Ca level or to immediate changes in urinary P excretion. In 2 patients with hypoparathyroidism slight depression of serum P occurred despite the increased serum Ca.

Normal subjects and those with osteomalacia and osteoporosis excreted less P on the day of the infusion than on earlier days, but in parathyroid disturbances P excretion was irregularly affected; one patient with post-operative hypoparathyroidism had increased P excretion, one with idiopathic hypoparathyroidism marked P retention, and in one with hyperparathyroidism due to a tumour, excretion increased slightly.

About 60 per cent. of the injected Ca was retained by normal subjects, more in osteomalacia and hypoparathyroidism.—D. Duncan.

HANSARD, S. L., COMAR, C. L. and DAVIS, G. K. Effects of age upon the physiological behavior of calcium in cattle. *Amer. J. Physiol.*, 1954, 177, 383-389. [Univ. Tennessee Atomic Energy Commission Agric. Res. Program, Oak Ridge.]

The cattle were 36 Herefords aged from 10 days to 190 months. Each received a single dose of ^{45}Ca by mouth or by vein and was killed after a 7-day balance experiment.

In all animals urinary ^{45}Ca excretion represented less than 0.5 per cent. of the dose. The 2 routes of administration permitted separation of curves for excretion of unabsorbed and endogenous Ca in the faeces. In animals aged 10 days and 1 month all ^{45}Ca given by mouth was absorbed. Excretion of unabsorbed ^{45}Ca was complete after 93 hr. in the animal aged 6 months and the time taken increased with age to 147 hr. The rate of excretion of endogenous ^{45}Ca , whether the dose was given by mouth or by vein, was 3 times as great in old as in young animals.

Equations are presented for the rate of disappearance of ^{45}Ca from the blood, which decreased with advancing age. The rate of exchange of Ca between plasma and tissues in cattle at 10 days, 6 months and 160 months of age was estimated at 102, 72 and 26 per cent. per min., respectively. The peak concentration of ingested ^{45}Ca in the blood was highest and occurred earliest in young calves and generally became lower and later with advancing age.

Age had no effect on the Ca content of soft tissues. Bone Ca content increased up to 18 months of age and then remained constant except in the vertebrae, where it continued to increase until old age. The Ca : P ratio was very constant at 1.94 ± 0.2 and the Ca : ash ratio at 0.38 ± 0.03 .

The tissue distribution of ^{45}Ca at different ages is tabulated. The percentage of exchangeable Ca in bone, calculated from specific activity values, tended to decrease with age.—D. Duncan.

MURTHY, G. K., DUSTUR, N. N. and RAY, S. C. Effect of feeding iodinated casein on calcium and phosphorus metabolism in young heifers. *Indian J. Dairy Sci.*, 1954, 7, 93-97. [Indian Dairy Res. Inst., Bangalore.]

In balance trials with Gir and Sindhi heifers iodinated casein given at the rate of 2 g. per 100 lb. bodyweight had no effect on the metabolism of Ca and P except for a slight improvement in absorption of P.—J. N. Attkin.

858

CHARLET-LÉRY, G., FRANÇOIS, A. C. and LEKROY, A. M. Utilisation digestive et rétention par le porc du phosphore et du calcium d'un phosphate naturel defluoré. [Absorption and retention by pigs of phosphorus and calcium from a natural phosphate defluorinated.] *Ann. Zootech.*, 1953, 2, No. 4, 285-301. [Lab. Recherches Zootech., Inst. Nat. Agronom., Paris.]

The details are presented of a balance experiment with 3 Large White pigs of approximately 30 kg. liveweight at the beginning. The basal ration was, per cent.: barley 30, manioc 35, oats 10, soya bean cake 5, meal 3, dried butter-milk 4, distillers' yeast 8, linseed cake 2 and alfalfa meal 3. In the first experimental period 1 per cent. pure CaCO_3 was added: in the next 4 periods 3 or 6 per cent. of a mixture of defluorinated phosphate 75, NaCl 15, MgCO_3 6.7, FeSO_4 3, CuSO_4 0.3. There was only 1 period with 6 per cent. and it had to be curtailed because of loss of appetite. The sixth period was without mineral supplement.

Absorption (intake less excretion in faeces) on the basal ration with CaCO_3 was for P 44.0 and for Ca 44.1 per cent.; and with the 3 per cent. supplement, roughly 33 per cent. of each. Corresponding retentions, as percentage of intake, were roughly P 43, Ca 40 and with the supplement 28 and 30. With a mean liveweight of 44.8 kg. and a mean rate of gain of 446 g. daily, the average retentions were 3.35 g. P and 7.06 g. Ca [reversed in para. 4° of summary], with a ratio of approximately 2 Ca : 1 P.—I. Leitch.

859

SHIRLEY, R. L., DRIGGERS, J. C., FEASTER, J. P. McCALL, J. T. and DAVIS, G. K. Effects of massive doses of P^{32} and Ca^{45} on laying hens. *Poultry Sci.*, 1954, 33, 612-615. [Dept. Animal Husb., Univ. Florida Agric. Exp. Stat., Gainesville.]

Year-old hens weighing 1500 to 1600 g. were given a complete laying ration. Two were injected with a total of 20.4 and 19.4 mC. ^{32}P , respectively, during 6 or 7 months; 2 other hens received a total of 32.5 and 30.5 mC. ^{45}Ca in the same time. No ill effect was observed in the next 2 years in the hens which received ^{45}Ca . The hens receiving the ^{32}P lost 200 g. liveweight, and died 11 and 12 days after the last and largest dose. When they died, 95 per cent. of the activity of the ^{32}P given had been expended. Post-mortem examination revealed haemorrhages in the heart, ovaries and magnum, necrotic right lobe of the liver, the presence of an abnormal green substance in the small intestine and blood in the caeca. There was no abnormality of bone, but a large concentration of the isotope was found there with no

apparent stratification. The blood of the hens given ^{32}P contained no monocytes or neutrophils during the 3 weeks before death and only occasional eosinophils and basophils. There was no effect on total red and white cell counts. Of the ^{32}P administered 43 per cent. was excreted within 10 days, but only 0.5 per cent. of the ^{45}Ca . Only 0.6 per cent. of the injected ^{32}P appeared in the eggs, and 14.5 per cent. of the injected ^{45}Ca . The bones contained 4 to 10 times as much ^{32}P as the soft tissues, the highest concentration being in the pubis, ilium and ischium.—M. J. Head.

DEVADATTA, S. C. and APPANNA, T. C. Availability of calcium in some of the leafy vegetables. *Proc. Indian Acad. Sci. [B]*, 1954, **39**, 236-242. [Christian Med. Coll., Vellore.]

Six groups of 4 to 6 rats were reared on a stock diet consisting of 2/3 whole wheat, 1/2 [1/3] whole milk powder, vegetables and supplements of vitamins A and D. At 28 days of age 1 group received a control diet of whole wheat 65, butterfat 10, skimmed milk powder 22, salt mixture 5 and maize starch 3 parts; the other 5 groups were given diets in which half the skimmed milk powder was replaced by ground dried leafy vegetables sufficient to provide the same amount of Ca as in the milk diet, the difference in weight being made up with maize starch. The 5 leafy vegetables used were Avati Keerai (*Sesbania grandiflora*), Mola Keerai (*Amaranthus gangeticus*), Chiru Keerai (*Amaranthus spinosus*), Karuvepilai (*Murraya koenigii*) and Murunga Keerai (*Moringa oleifera*). At 60 days of age the rats were killed and their carcasses were analysed for Ca.

The carcasses of the rats on the control diet and diets containing the dried vegetables contained, respectively, 0.764, 0.820, 0.787, 0.807, 0.906, and 0.810 per cent. of Ca. Availability of Ca, calculated from the ratio of Ca retention to Ca intake, was for the 6 diets, respectively, 0.85, 0.74, 0.78, 0.79, 0.54 and 0.69. Only the Ca of Karuvepilai was utilised by the rat significantly less well than that of milk; the Ca in the other 4 vegetables was utilised almost as well as that of milk. All 5 vegetables were good sources of Ca.—G. F. Garton.

TAYLOR, T. G., MOORE, J. H. and TOMLIN, D. H. Exchange of bone calcium and phosphorus *in vivo*. *Nature*, 1954, **173**, 1137-1138. [Dept. Agric. Chem., Univ. Reading.]

Vol. 25, No. 1

Four laying pullets 8 months of age received a diet low in Ca; birds 1 and 2 laid 6 eggs and were estimated to have lost 38 per cent. of their skeletal Ca, birds 5 and 7 laid 2 eggs each and lost 15 and 17 per cent. Birds 3 and 8 received a ration high in Ca and were killed after laying 3 eggs. All the diets contained ^{45}Ca and ^{32}P . The specific activities of the elements were compared in cortical and medullary bone, since the latter undergoes rapid destruction and formation and is thus a suitable standard against which the activity of cortical bone may be judged.

There was a pronounced reciprocal relation between the exchange figures obtained for the 2 elements, and the figures were similar in magnitude to those obtained in an earlier study with young rats (Abst. 814, Vol. 24), so it is considered that "incorporation of tracers into bone minerals by exchange does not occur to such an extent as to preclude their use in studies of bone growth."

D. Duncan.

KAPLANSKII, S. YA., ZAMYATKINA, O. G. and KHESIN, R. V. K voprosu o vliyaniy belkovoi nedostatochnosti na skorost' obmena fosfornykh soedinenii v organizme zhivotnykh. [The effect of protein insufficiency on the rate of metabolism of phosphorus compounds in the animal organism.] *Biokhimiya*, 1953, **18**, 552-558.

Rats, on a diet containing 3 per cent. protein, were injected subcutaneously with dibasic sodium phosphate (^{32}P) after they had lost from 25 to 30 per cent. of their weight. Three hours later they were killed and tissues were analysed for ^{32}P and compared with those from control animals. Blood volume was estimated in one group by the dye method, and in another by injection of radio-active red cells.

In normal rats, blood volumes expressed as percentage of bodyweight were similar by both methods. In the protein-deficient animals the figure by the dye method was higher, but that by the red cell method was normal.

In deficient animals P uptake by the bones was much reduced, giving a higher blood level of ^{32}P than in controls, and hence a higher rate of uptake by other tissues. In animals returned to full diet after protein depletion, normal figures were again obtained.—D. W. Taylor.

WILSON, G. M., OLNEY, J. M., BROOKS, L., MYRDEN, J. A., BALL, M. R. and MOORE, F. D. Body sodium and potassium. 2. A comparison of metabolic balance and isotope dilution methods of study.

MOORE, F. D., EDELMAN, I. S., OLNEY, J. M., JAMES, A. H., BROOKS, L. and WILSON, G. M. 3. Inter-related trends in alimentary, renal and cardiovascular disease; lack of correlation between body stores and plasma concentration. *Metabolism*, 1954, 3, 324-333; 334-350. [Surg. Res. Lab., Peter Bent Brigham Hosp., Boston, Mass.]

For part 1 see Abst. 202, Vol. 25.

2. Studies were made on 16 subjects, 1 a normal student and the others patients with fractures (2), burns (1), duodenal ulcer (2), carcinoma (5), mitral stenosis (3), stricture of the common duct (1) and Cushing's syndrome (1). Na intake in a normal adult man is about 150 m. equiv. and K intake about 100 m. equiv. daily. Balance changes of that magnitude occur only after surgical interventions. Total body exchangeable Na and K are of the order of 2800 to 3000 m. equiv.

In all there were 27 paired records of Na exchange and balance, giving 17 comparisons in 10 patients. For K there were 35 paired records, giving 22 comparisons in 13 subjects. Agreement was within 125 m. equiv. a week in 33 of the 39 comparisons. The exceptions are discussed in detail. For both Na and K the balance technique tended to show greater retention or smaller loss than the isotope dilution method. The mean differences were not significant.

The chief disadvantage of the balance technique is that systematic errors are cumulative and the technique is subject to such errors from errors in food analysis or measurement of intake or output or analysis of excreta. In practice it has been found that balances of K tend to be slightly positive continuously, even in adults. On the other hand, isotope measurements have a random error that is not cumulative. The balance method is more sensitive for small changes; the isotope dilution method is much more reliable for serial measurements and gives a measure also of total body composition. Exchangeable Na excludes about 55 per cent. of the Na in bone, exchangeable K is about 95 per cent. of the total in the body.

3. When estimates of exchangeable Na and K

are combined with measurements of body water with deuterium, "total exchangeable hydrogen", and changes in bodyweight, light is thrown on "deficiencies" and their diagnosis. Tables summarise normal values of exchangeable Na and K in men and women, values found in obese subjects and subjects with disorders of the alimentary tract, renal failure, mitral stenosis or hypertension with and without oedema. The main findings are as follows:

The normal woman has less exchangeable K than the normal man because she has more fat and less muscle; the same is true of the obese. Chronic disease of the alimentary system with wasting gives the results to be expected from loss of fat, loss of muscle or both. Severe restriction of Na intake reduces blood pressure but, in a small group of subjects with severe hypertension, total exchangeable Na was within normal limits and changes in blood pressure showed no relation to change in total exchangeable Na. In oedema, exchangeable Na is greatly increased and K is reduced in consequence of muscle wasting. There was no correlation between serum values for Na and K and total exchangeable amounts in the body; they varied independently and sometimes inversely.—I. Leitch.

BERGSTROM, W. H. and WALLACE, W. M. Bone as a sodium and potassium reservoir. *J. Clin. Invest.*, 1954, 33, 867-873. [Dept. Paediat., Harvard Med. Sch., Boston, Mass.]

Acute sodium depletion and acidosis were induced in rats by intraperitoneal dialysis. A solution containing glucose and ammonium chloride was injected intraperitoneally and 4 hr. later as much peritoneal fluid as possible was withdrawn. The animals were killed 48 hr. after the injection and the long bones were removed for analysis.

The quantities of Ca, Na, and K present in treated adult rats were 7800, 119 and 10 m. equiv. per kg. bone, respectively, and in controls 8000, 173 and 30. In young rats, about 100 g. live-weight, the relative loss of each element was about 20 per cent. of that originally present.

The effect of severe dietary Na restriction on the composition of bone in rapidly growing rats was also studied. The Ca concentration was not affected, but that of Na was half that in controls and that of K even less.—R. Hill.

BULL, J. P. and ENGLAND, N. W. J. Fluid and electrolyte exchange in patients with burns. *Lancet*, 1954, 267, 9-17. [Med. Res. Comm. Indust. Injuries, Birmingham Accident Hosp.] The subjects were 33 patients aged from 13

N.A. and R., January 1955

months to 82 years with burns involving 12 to 69 per cent. of the body surface. All were undergoing routine treatment. Retention of Na and water usually occurred during the first few days. Older patients showed a greater tendency than younger to retain fluid. The volume of urine produced in the first 48 hr. was influenced by intake of non-colloid fluid, but in patients with large burns the large amount of non-colloid fluid required to increase urine output may be clinically undesirable. Moderately negative K balances, noted in the first few days, were readily corrected by increased intake. There was no sustained anuria and no indication of tubular lesion.

TATUM, H. J. **Compartmental distribution and shift of water and electrolytes in pre-eclampsia. 1. Distribution of electrolytes in the serum and edema fluid.** *Amer. J. Obstet. Gynecol.*, 1954, **67**, 1197-1201. [Dept. Obstet. Gynaecol., Sch. Med., Louisiana State Univ., New Orleans.]

Na, K and chloride were estimated in serum from 44 patients with pre-eclampsia and 36 controls, and in oedema fluid obtained from pre-tibial subcutaneous tissue from 39 oedematous patients, of whom 31 were considered to have pre-eclampsia. All were in the last third of pregnancy. The mean level of serum Na in the pre-eclamptics was 137.5 m. equiv. per litre, range 116.4 to 149.8, and in the normal controls 142.3, range 136.7 to 146.9. The difference is highly significant. A significant reduction of serum chloride levels was also found in pre-eclampsia. Serum K levels were unaffected. In pre-eclampsia the Na content of oedema fluid was higher than that of serum, the average difference being 2.05 m. equiv. per litre; in the controls it was lower, difference 0.58 m. equiv. per litre. In both groups K levels were lower in oedema fluid than in serum, and chloride levels were higher. These findings add to the evidence that Na retention in pre-eclampsia is accompanied by withdrawal of Na from the serum to the tissue fluid, and that shifts of Na and chloride are not reciprocal. The data do not point to any great disturbance of K metabolism in pre-eclampsia.—A. M. Thomson.

869

SCHLEGEL, J. U. **Return of sodium loads in normal subjects following restricted sodium intake.** *Surgery*, 1954, **35**, 848-856. [Sch. Med. Dent., Univ. Rochester, N.Y.]

The proportion returned of an Na load given by mouth to subjects previously on a low-Na diet showed a gradual drop, increasing with the length of time they had been on low Na intake. The return, which might be down to about 20 per cent.

after only 2 days of Na-deficient diet, was independent of the magnitude of the Na load and of the total Na loss in the urine before the load was given. Two days of starvation were sufficient to reduce the return of an Na load to 25 per cent. of the normal.

The results indicate the undesirability of restricting the Na intake of a patient pre-operatively for any length of time, since this may aggravate post-operative salt retention. It is suggested rather that the patient pre-operatively should get adequate amounts of Na as well as of K, since this may prevent any extensive drop in serum Na induced by the stress.—M. B. Richards.

HANSEN, J. D. L. and BROCK, J. F. **Potassium deficiency in the pathogenesis of nutritional oedema in infants.** *Lancet*, 1954, **267**, 477. [Dept. Med., Univ. Cape Town, S. Africa.]

Six infants with nutritional oedema associated with incorrect post-weaning feeding and diarrhoea were the subjects of Na, K, Cl and N balance studies. Some of the infants apparently had kwashiorkor. All had low blood albumin and were treated with skimmed milk preparations.

From the start of treatment there was retention of K and N in the ratio of 9:1 for the first 3 days and thereafter of 3.5:1. There was an initial small retention of Na and Cl and a gain in weight followed by considerable losses accompanied by diuresis, loss of weight and loss of oedema. Two infants were given a mixture of Na and K salts with glucose and water for 4 and 5 days before milk feeding was begun. During this time K was retained and a negative balance of water, Na and Cl, with modification of the oedema, was obtained. There was no change in serum protein during this period.

Serum K was below normal on admission and rose with treatment. Serum Na was not related to degree of oedema or to treatment.—F. C. Aitken.

873

CORT, J. H. and MATTHEWS, H. L. **Potassium deficiency in congestive heart-failure. Three cases with hyponatraemia, including results of potassium replacement in one case.** *Lancet*, 1954, 266, 1202-1206. [Dept. Physiol., Med. Sch., Birmingham.]

Resistance to mercurial diuretics developed in 3 patients with congestive heart failure. All 3 showed low serum Na and Cl levels and were in strongly negative K balance. Alkalosis was suspected, as the serum bicarbonate:chloride ratio was increased. Estimation of electrolytes in muscle biopsy material showed that the tissue cells were grossly deficient in K and were over-hydrated; their Na content was normal or slightly raised. The K deficiency was calculated to be about 800 m. equiv. in one of the patients.

Potassium therapy was studied in one patient; when small doses were given there was retention of K and a rise in serum Na and in urinary volume, but the urine remained Na-free. When the dose of K was increased there was a further rise in serum Na and Cl and in urine volume and finally the serum chemistry became normal and Na appeared in the urine; at this time a further muscle biopsy showed increased intracellular K and lowered intracellular Na and water. As the serum and muscle chemistry became normal the clinical condition improved. The role of K depletion in this condition is discussed.—L. Wills.

875

SPARGO, B. **Kidney changes in hypokalemic alkalosis in the rat.** *J. Lab. Clin. Med.*, 1954, 43, 802-814. [Dept. Pathol., Univ. Chicago, Ill.]

The K reserves of 3-month-old male rats were reduced by protein depletion. The rats were then maintained on a low-K, high-Na diet, with amino-acids as the source of N, and kept in positive N balance. They were fed by tube to ensure equal intakes. Control rats received K in place of Na in the diet.

The 2 groups remained comparable for 4 days, except that the low-K high-Na group drank and excreted more water, the urine becoming neutral in reaction. Thereafter animals of this group became indolent, and developed distended abdomens and muscular weakness, even foreleg paralysis. Faeces retention increased, but weight

gains were steady and comparable with those of the controls. Deaths, apparently from cardiac decompensation, began on the tenth day.

Every other day from the fourth onwards, 2 K-deficient rats and a control were killed. Carcase analysis showed no difference in water, fat or protein, and blood Hb and total serum protein remained constant. In the low-K group, K excretion fell sharply on the fourth day, and Na excretion on the ninth day, at which time also water intake and output returned to the level of the controls. Alkalosis developed on the fourth day and increased in severity, and blood N.P.N. increased progressively.

Kidney weight gradually increased in the low-K group, but this was not accompanied by changes in the levels of water, fat or protein. The first microscopic changes appeared on the sixth day, with increased mitoses in the collecting tubules, hydropic change and some dilation of the tubules in the mid-medullary zone. Ca casts were seen at 8 days. Maximum changes, seen at 14 days, were increased lumen size in the distal and collecting tubules with severe hyaline droplet change in the collecting tubules and an increase in the number and size of the cells in the tubular wall, with evidence of regeneration. Indeed, proliferative changes far exceeded degenerative changes. No change was seen in the glomeruli. The collecting tubules near the papillae showed coarse granular intracellular substances, probably glycoproteins. Small fat droplets were evident in the junctional zone. Alkaline phosphatase was reduced, but acid phosphatase and esterase were unchanged.

Heart lesions were constantly found after 6 days, and became increasingly severe, but there was no change in the glycogen content of cardiac muscle. Pituitary and adrenals showed no change.

When similar rats were kept in negative N balance, the lesions of K deficiency were slight and irregular. It is suggested that this is because utilisation of tissue protein released K.

HAM, M. P. and SMITH, M. D. **Fluorine balance studies on four infants. Fluorine balance studies on three women.** *J. Nutrition*, 1954, 53, 215-223; 225-232. [Dept. Food Chem., Univ. Toronto, Ont.]

Fluorine balances were studied in 4 healthy male infants. At the time of the first 3-day balance test the infants were 6 to 14 weeks old and received milk only; at the second test they were 16 to 18 weeks old and received in addition to the milk 32 to 50 g. Pabulum daily.

N. A. and R., January 1955

In the first period 3 infants retained F and the fourth infant was almost in balance; in the second period all retained F. The percentage of dietary F retained was from - 2 to + 29, mean + 16, in the first period and from 22 to 50, mean 34, in the second. The total F intake in the second period was between 476 and 706 μg . daily.

In the second study the subjects were 3 women aged 23 to 24 years. F balances were studied in three 3-day periods; on normal diet, but avoiding food high in F such as tea and fish; on a diet including 70 g. Pabulum daily; and on a diet including 1360 to 1815 ml. tea infusion daily. The daily F intakes in the 3 periods were 429 to 792, 946 to 1435 and 1200 to 1368 μg ., respectively.

The mean F retention in the 3 periods was 43, 33 and 40 per cent., respectively, and the percentage excreted in the urine 34, 22 and 44. If faecal F is unabsorbed, absorption was only 55 per cent. on Pabulum diet, and reached 84 per cent. when tea was taken.—D. Duncan.

877

WADHWANI, T. K. Effect of fluorine on the composition of bones: changes in the composition of bones of rats. 1. *Proc. Indian Acad. Sci. [B]*, 1954, 39, 223-235. [Sect. Pharmacol., Indian Inst. Sci., Bangalore 3.]

Young rats were fed on a complete diet with 2 mg. NaF daily. A control group without NaF was offered the amount of food consumed by the experimental group.

F decreased the N content of dry fat-free bone and increased the Na and carbonate contents. Increasing the F to 4 mg. daily exaggerated these effects but also increased the Ca and in most bones also the P content.

The effects of F in N or Ca and P deficiency were similar, but usually greater than those produced on a balanced diet.—R. Hill.

878

KONO, K. [Influence of chronic fluorosis on the bone growth, particularly on the epiphyseal cartilage (Report 2). The growth and bone changes of growing rats fed on varied contents of fluorine.] *Shikoku Acta Med.*, 1954, 5, 30-39. [Dept. Int. Med., Sch. Med., Tokushima Univ.] In Japanese: English summary.

Rats aged 30 to 50 days were given a standard Sherman diet alone or with 375, 100, 50, 10, 5 or 2 p.p.m. F as sodium fluoride. Groups were killed at intervals of about a month.

Rats receiving 2 or 5 p.p.m. F grew better than controls; those receiving 50 p.p.m. or more grew less well. The groups receiving 2 or 5 p.p.m. showed premature synostosis of epiphyseal cartilage and good development of bones and trabe-

culae. With 50 p.p.m. or more the trabeculae and cortex became thinner and osteoporosis developed, while synostosis was retarded. Cells in the epiphyseal cartilage showed atrophy and pyknosis. (From summary.)—D. Duncan.

879

IOHICAWA, M. [Histochemical studies on the changes of calcium and alkaline phosphatase in experimental fluorosclerosis of rats.] *Osaka Daigaku Igaku Zasshi*, 1954, 6, 243-254. [Dept. Pub. Health, Wakayama Med. Coll.] In Japanese: English summary.

Rats were given a diet containing 1, 5, 10, 50 or 100 p.p.m. F and were killed after 107, 192 or 210 days. Alkaline phosphatase and calcium deposition in the distal ends of femurs were examined histochemically by the method of Shimizu and Anzono [reference given in Japanese].

At the levels of 50 and 100 p.p.m. phosphatase activity was greatly reduced in the periosteum, Haversian and Volkmann's canals and epiphyseal plate; at the lower levels of 5 and 10 p.p.m. there was reduction only if the period of administration was prolonged. The calcium reaction of bone shafts, trabeculae and epiphyseal plate was negative at the lower and positive at the higher, 50 or 100 p.p.m., levels, but after prolonged administration of F a positive reaction was obtained also with 5 or 10 p.p.m. (From English summary.)

BÉLANGER, L. F., LOTZ, W. E., VISEK, W. J. and COMAR, C. L. Autoradiographic visualization with Ca^{45} of normal growth of the incisor of pigs and the effect of fluorine feeding. *Anat. Rec.*, 1954, 119, 53-69. [Dept. Histol., Univ. Ottawa.]

Five hours after the injection of ^{45}Ca , autoradiographic lines were visible in the incisor teeth of normal pigs at the limit of predentine and dentine, and at the outer surface of the cement. Ten days after injection the lines were displaced from their original positions, and more so after 45 days. Animals fed on diets containing 200 p.p.m. NaF_2 showed no great difference from the normal if fed to appetite, but on restricted feeding there was retardation of the growth of dentine and cement. In all pigs given 1000 p.p.m. NaF_2 there was marked retardation in the growth of dentine, cement and alveolar bone, and a coarse wavy pattern of the autoradiographic band appeared over dentine. These defects are apparently related to toxicity and abnormal mineral deposition.

ZIPKIN, I. and MCCLURE, F. J. Cariostatic effect and metabolism of ammonium fluosilicate.

Pub. Health Rep., Washington, 1954, 69, 730-733. [Lab. Oral Biol. Chem., Nat. Inst. Dent. Res., Pub. Health Serv.]

Ammonium fluosilicate was studied when supplying 50 p.p.m. F in the drinking water of rats and its effects were compared with those of NaF alone or of a composite mixture of NaF, sodium silicate and ammonium carbonate which supplied the same concentration of Si and NH_4 ions as did the fluosilicate. A cariogenic diet (see Abstr. 923, Vol. 22) was given to the 3 experimental groups and to a control group, each with 30 rats, and after 99 days the animals were killed, the degree of caries was assessed and ash and F were estimated in bones and teeth. There was no gross evidence of toxicosis in the rats, and no difference in the rate of growth of the different groups.

Ammonium fluosilicate was as effective as NaF in preventing caries and, because of its cheapness and solubility, is considered suitable for the fluoridation of municipal water supplies.

D. Harvey.

882

CARR, L. M. A method controlling dental caries in rats by injections of sodium fluoride. *Dent. J. Austral.*, 1954, 26, 51-56. [Commonwealth Dept. Health, Canberra.]

Female hooded rats were given a high-sucrose diet and 40 of their offspring were divided among 5 groups before weaning. Treatments for these during the period between calcification and eruption of first and second molars were: (1) no fluoride, (2) 0.24 mg. fluoride on fifteenth day of age, (3) 0.24 mg. on each of fifteenth, sixteenth and seventeenth days, (4) 0.12 mg. and (5) 0.024 mg. also on these 3 days. Sodium fluoride was injected parenterally and was equivalent to 20, 20, 10 and 2 mg. per kg. bodyweight. At 21 days the rats were weaned and for 8 weeks they were given a coarse-particle diet with 67 per cent. maize meal, followed by a high-sucrose diet with 60 per cent. sugar, after which they were killed. Caries was studied by a modification of the technique of Cox *et al.* (Abstr. 4523, Vol. 9).

In the control group the number of carious lesions per rat was 7.1 and in the experimental groups 7.6, 4.7, 5.4 and 6.6, respectively. Changes in incidence were only slight in groups 2 and 5 but in groups 3 and 4 the incidence was 34 and 24 per cent. less than in the control group. The percentages of lower first and second molars with gross caries were 21, 20, 8, 5 and 25 in the respective groups; in groups 3 and 4 none of the upper molars was grossly affected.

The differences, although not statistically significant, suggested that the incidence of caries in rats might be reduced by administering large quantities of fluoride between the time of com-

pletion of calcification of the enamel and eruption of the tooth.—D. Harvey.

MITTLER, S. and BENHAM, G. H. Nutritional availability of iodine from several insoluble iodine compounds. *J. Nutrition*, 1954, 53, 53-58. [Armour Res. Found., Inst. Technol., Chicago, Ill.]

Any insoluble iodine compound which can be incorporated in an animal salt lick without toxic effect has a distinct advantage in that the I cannot be leached out on exposure to weather.

Five female albino rats of 35 to 50 g. were reared on a low-iodine diet, and 10 comparable animals were fed on this diet plus 265 μg . I as KI per kg. food. Another 3 groups of 10 were given the same amount of I as Cu_2I_2 , diiodo-dithymol or 3-5-diiodosalicylic acid mixed in the food. At the end of 5 weeks the control rats had an average thyroid weight of 15.4 ± 3.5 mg. per 100 g. bodyweight. The other 4 groups had average thyroid weights of 10.0 ± 1.1 , 9.8 ± 1.9 , 12.5 ± 2.4 and 11.9 ± 1.4 mg. per 100 g. bodyweight, respectively. All 3 insoluble compounds had provided nearly the same amount of I as the KI and prevented enlargement of the thyroid to about the same extent.

In another test 4 groups of rats were fed on the same diet plus 265, 200 and 150 μg . I as Cu_2I_2 per kg. food. The controls had thyroids averaging 18.1 ± 2.1 mg. per 100 g. bodyweight, and the experimental groups thyroids averaging 7.3 ± 1.8 , 8.5 ± 2.2 and 9.2 ± 2.4 mg. per 100 g. bodyweight, respectively. As little as 1.5 μg . I as Cu_2I_2 per day prevented enlargement. Acute and chronic toxicity studies on Cu_2I_2 and 3-5-diiodosalicylic acid showed that these compounds were not toxic in the amounts required to protect the thyroid gland from I deficiency.—B. W. Simpson.

886

JOHNSTON, F. A., INGALLS, R. L. and MUKA, B. O. The use of $\alpha\alpha'$ -dipyridyl for determining the

N.A. and R., January 1955

amount of ferrous iron formed in the digestive tract of women before and after the addition of beef to the diet. *J. Nutrition*, 1954, **53**, 83-91. [New York State Coll. Home Econ., Cornell Univ., Ithaca.]

Two healthy women, aged 36 and 50 years, were given for 6 days a diet adequate in energy and protein and as complete in other respects as possible but low in Fe. On the seventh and the eighth day 0.15 g. $\alpha\alpha'$ -dipyridyl was given by mouth; the subjects were kept on the low-Fe diet for 2 more days. The same procedure was then repeated with 300 g. ground beef substituted for part of the sugar in the low-Fe diet.

The Fe content of the faeces did not rise on administration of $\alpha\alpha'$ -dipyridyl with either diet. This indicated that $\alpha\alpha'$ -dipyridyl did not combine with ferrous Fe in the digestive tract to form an insoluble compound and therefore cannot be used to measure the amount of ferrous Fe formed. One subject absorbed 4 per cent. and one 35 per cent. of the Fe of the beef.—G. F. Garton.

887

GRACE, W. J., DOIG, R. K. and WOLFF, H. G. (with STEINHOUSE, D. W.) Absorption of iron from the gastrointestinal tract. *J. Clin. Nutr.*, 1954, **2**, 162-167. [Dept. Med., New York Hosp.-Cornell Med. Centre, New York.] Spanish summary.

Serum Fe level, estimated 2 hr. after administration of 2 mg. Fe per kg. by mouth, in 7 healthy subjects was 192 μg . per 100 ml. after ferrous Fe and 166 μg . per 100 ml. after ferric Fe. No difference resulted from simultaneous administration of bicarbonate. In a subject with gastric fistula, as in the healthy subjects, Fe absorption varied widely from day to day, lower values being obtained with ferric than with ferrous salts. The levels were almost the same when the pH of the gastric contents was about 2 as when it was between 5 and 8 after administration of Na bicarbonate.

Absorption of Fe is not necessarily related to acidity of the stomach contents, but is probably related to the absorptive capacity of the upper gastro-intestinal tract. The difference in the absorption of ferric and ferrous Fe is probably not of clinical importance.—M. B. Richards.

888

BOTHWELL, T. H., VAN DOORN-WITKAMPF, H. VAN W., DU PREEZ, M. L. and ALPER, T. The absorption of iron. Radioiron studies in idiopathic hemochromatosis, malnutritional cytosiderosis, and transfusional hemosiderosis. *J. Lab. Clin. Med.*, 1953, **41**, 836-848. [Dept. Med., Univ. Witwatersrand, Johannesburg.] Absorption of radio-active Fe was studied in 5

patients with idiopathic haemochromatosis, 5 with malnutritional cytosiderosis, 3 with transfusional haemosiderosis, and 8 controls with no anaemia. Increased Fe absorption was found in the first group, part of the absorbed Fe being used for Hb formation and the remainder being deposited in the liver and other organs. Neither phosphates nor fat-soluble vitamins influenced the rate or pattern of absorption. In the second group absorption of Fe from the gut seemed low in 4 subjects; in the other there was a significant uptake by blood, and abnormal deposition in the liver. In the third group Fe absorption was not completely absent, but Hb utilisation was very low in 2 patients. Apparently absorption of Fe may continue in spite of saturated body Fe stores. In the control group there was wide variation in the level of radio-active Fe in the Hb, and the evidence suggested that all the absorbed Fe was not being immediately used for Hb formation.

REMY, D. Der Eisenstoffwechsel bei der Hämo-chromatose. [Iron metabolism in haemochromatosis.] *Deutsch. med. Wochenschr.*, 1954, **79**, 1042-1044. [Med. Klin., Städt. Krankenanst., Bremen.]

In haemochromatosis absorption of Fe is not controlled as in normal subjects. Values for transferrin are low normal and synthesis of ferritin appears to be normal. Serum Fe is high and the movement of Fe from blood to tissues is greatly accelerated. Excretion appears to be normal. The cause of the disease is not known and hence treatment must be directed simply to controlling Fe supply and accumulation. Treatment by blood letting with return of plasma and a diet of low Fe content is recommended.—I. Leitch.

890

STERN, P., KOŠAK, R. and MISIRLIJA, A. Beitrag zur der Eisenresorption. [Absorption of iron.] *Experientia*, 1954, **10**, 227. [Pharmakol. Inst., Univ. Sarajevo.] English summary.

Rabbits of 1500 to 3000 g. liveweight received 30 mg. terramycin and 25,000 I.U. penicillin daily. After 3 to 4 days bacterial tests of the stools were negative except for the presence of *Proteus vulgaris*. Other animals were rendered anaemic by bleeding and similarly treated. All then received 30 mg. FeSO_4 per kg. bodyweight. Serum analysis 18 hr. later showed no Fe absorption. Absorption was restored by the addition to the diet of strains of *Bact. coli* or of enterococci resistant to terramycin.

transport. *Amer. J. Physiol.*, 1954, **178**, 45-48. [Dept. Anat., Sch. Med., Univ. Washington, Seattle.]

With radio-active Fe in rats evidence was obtained supporting an earlier observation that the lymphatics are not involved in Fe absorption and transport.—R. Hill.

892

SPOENDLIN, H. Die enterale Eisenaufnahme und Speicherung bei Mangeldiät und toxischer Leberschädigung im Tierversuch. [Absorption of iron from the digestive tract and storage of iron with a defective diet and liver damage due to poisoning in animal experiments.] *Ztschr. ges. exp. Med.*, 1954, **124**, 131-145. [Inst. Pathol., Univ. Zürich.]

Rats on otherwise normal diet with added Fe thrived well, and only after 20 to 23 weeks were the first particles of haemosiderin visible in the liver cells of the periportal zone. On a maize diet with the same amount of Fe, haemosiderin particles were found in the liver cells after 7 weeks, with a rapid increase in the next few weeks. Apparently the deficient diet caused a disturbance of regulation of Fe absorption by the intestinal mucosa. Fe storage occurred only in the periportal liver cells. Thus a liver cell block, in the same sense as the intestinal block, appeared to hinder excessive Fe storage, and this block was not noticeably disturbed by the maize diet. In rats on the maize diet which received injections of CCl_4 there was little deposition of haemosiderin in the liver. Apparently only functionally active liver cells are capable of storing Fe. Thus haemosiderin storage is to be regarded as the expression of a healthy, functionally active cell, and not as a sign of injury or degeneration, as in fatty liver. In the maize-Fe group there was haemosiderosis of the distal convoluted tubules of the kidneys, such as is found in haemochromatosis. This differs from the effect of Fe given parenterally.—M. B. Richards.

LAHEY, M. E., GUBLER, C. J., BROWN, D. M., SMITH, E. L., JAGER, B. V., CARTWRIGHT, G. E. and WINTROBE, M. M. Studies on copper metabolism. 8. The correlation between the serum copper level and various serum protein fractions. *J. Lab. Clin. Med.*, 1953, **41**, 829-835. [Dept. Med., Coll. Med., Univ. Utah, Salt Lake City.]

Electrophoretic analyses of the sera of 19 subjects with serum Cu values ranging from 24 to 402 μg . per cent. showed a high correlation between serum Cu and the $(\alpha_2 + \alpha_3)$ -globulin fraction ($r = +0.79$), and good correlation between Cu and the $(\beta_1 + \beta_2)$ -globulin fraction ($r = +0.62$). The samples included umbilical vein serum (low Cu), normal serum, serum from pregnant women and from patients with infections and leucaemia (high Cu). No significant correlation was observed between serum Cu and other protein fractions estimated electrophoretically. No significant correlation was observed between serum Cu and total mucoproteins in 33 subjects, or between serum Cu and total proteins, albumin and globulin estimated by a standard salt fractionation method in 110 subjects with Cu values varying from 63 to 291 μg . per cent. Electrophoretic analyses of rat sera gave results contrasting with those in human subjects in that a high correlation was found between plasma Cu and the α_2 -globulin fraction ($r = +0.76$), and little or no correlation between $(\alpha_2 + \alpha_3)$ -globulin and Cu. In the rat as in man a high degree of correlation ($r = +0.80$) was found between Cu and the $(\beta_1 + \beta_2)$ -globulin fraction.

M. B. Richards.

896

GUBLER, C. J., TAYLOR, D. S., EICHWALD, E. J., CARTWRIGHT, G. E. and WINTROBE, M. M. Copper metabolism. 12. Influence of manganese on metabolism of copper. *Proc. Soc. Exp. Biol. Med.*, 1954, **86**, 223-227. [Dept. Med., Coll. Med., Univ. Utah, Salt Lake City.]

The administration of large amounts of Mn to rats initially weighing about 100 g. reduced growth. Urinary excretion of Cu was less and concentration of Cu in plasma and brain higher than in control rats. Microcytic hypochromic anaemia was present.

In similar rats given large amounts of Cu, growth was almost normal and all tissues studied, except brain, contained abnormally high concentrations of Cu. There was no anaemia.

Simultaneous administration of Mn and Cu reduced growth more than Mn alone, and the concentrations of Cu in tissue were all greater than those produced by Cu alone. Anaemia similar to that produced by Mn was present in these animals.

R. Hill.

897

VAN KOERTSVELD, E. E. Enkele aspecten van de koperstofwisseling. [Some aspects of copper metabolism.] *Tijdschr. Diergeneesk.*, 1954, 79, 495-504. [Inst. Moderne Veevoeding "de Schothorst", Hoogland.] English, French and German summaries.

The literature dealing with the Cu of blood and tissues investigated with ^{64}Cu is reviewed. Cu is absorbed from the upper small intestine and, because of the nature of the portal circulation, it will be deposited preferentially in the right lobe of the liver. The same will be true in the ruminant unless Cu is absorbed from the true stomach, and that has not been shown. Liver biopsy to assess Cu stores is unreliable since Cu may be unevenly distributed. Cu is involved in the formation of both hair pigments and hair keratin. The estimation of Cu in clean hair, shorn periodically, is a good index of Cu supply. Data will be published for both Cu and Mn in cattle hair (see Title 4665, Vol. 24).—I. Leitch.

898

DICK, A. T. Studies on the assimilation and storage of copper in crossbred sheep. *Austral. J. Agric. Res.*, 1954, 5, 511-544. [Div. Animal Health Prod., C.S.I.R.O., Animal Health Res. Lab., Parkville, Victoria.]

Storage of Cu in the livers of wether sheep aged 1 to 2 years was proportional to the amount eaten as copper sulphate over the range 3 to 20 mg. Cu daily. The quantity stored in 6 months was 4.5 to 5.0 per cent. of intake. Blood Cu concentration was not affected by these levels of Cu intake.

The addition of ferrous sulphide to a high-Cu diet greatly reduced Cu storage. This was apparently due to the formation of insoluble copper sulphide, since Cu given as sulphide did not increase the liver content. Neither elementary S nor thio-sulphide reacted like sulphide in reducing Cu storage.

The effects of Zn and Ni on Cu assimilation were small, but Mo as ammonium molybdate significantly reduced liver Cu. This effect was greatly increased by high concentrations of sulphate in the diet.—R. Hill.

GRAY, L. F. and DANIEL, L. J. Some effects of excess molybdenum on the nutrition of the rat. *J. Nutrition*, 1954, 53, 43-51. [U.S. Plant, Soil Nutrit. Lab., Bur. Plant Indust., U.S. Dept. Agric., Ithaca, N.Y.]

The effects of vitamin B_{12} , methionine and Cu on the retardation of growth produced by excess Mo in the diet were studied. Vitamin B_{12} did not increase growth over that produced by the basal diet without Mo but it reduced significantly the growth-retarding effect of Mo.

Either methionine or Cu reduced the growth-retarding effect of Mo, methionine more effectively than Cu, but growth was not greater with both methionine and Cu added to the Mo diet than with methionine alone.

None of the additions completely eliminated the effect of Mo.—R. Hill.

WASE, A. W., GOSS, D. M. and BOYD, M. J. The metabolism of nickel. I. Spatial and temporal distribution of Ni^{63} in the mouse. *Arch. Biochem. Biophys.*, 1954, 51, 1-4. [Div. Biol. Chem., Hahnemann Med. Coll., Philadelphia, Pa.]

Intraperitoneal injections of ^{63}Ni were given to 56 mice and groups were killed at intervals after injection.

Ni was widely distributed through the body, though only small quantities were found in brain and muscle. Retention was greatest in lung and brain.—R. Hill.

902

KULWICH, R., PEARSON, P. B. and LANKENAU, A. H. Effect of coprophagy upon S^{35} uptake by rabbits after ingestion of labeled sodium sulfate. *Arch. Biochem. Biophys.*, 1954, 50, 180-187. [Bur. Animal Indust., U.S. Dept. Agric., Beltsville, Md.]

Six rabbits aged 7 to 12 weeks, maintained on commercial pellets, were given by stomach tube less than 12 μg . carrier-free sulphate containing 150 to 300 μC . ^{35}S . Each animal was then kept in a metabolism cage which allowed the separation of urine and faeces; these were collected quantitatively. Three of the animals were fitted with wooden collars to prevent coprophagy. After 4 days all 6 were killed and ^{35}S was estimated in urine, faeces and selected tissues.

In both collared and uncollared animals about 65 per cent. of the ^{35}S given was excreted in the urine within 4 days; in the uncollared rabbits the faecal excretion of ^{35}S was less than in the collared rabbits. Coprophagy also produced a considerable increase in the uptake of ^{35}S by the blood.

Collar wearing did not reduce the uptake of ^{35}S in cartilaginous tissue, but the ^{35}S content of liver, muscle, brain, kidney, and blood was much less.
G. F. Garton.

HOOPER, J. M. D., EVANS, I. W. J. and STAPLETON, T. Resting pulmonary water loss in the newborn infant. *Pediatrics*, 1954, 13, 206-210. [Paediat. Unit, St. Mary's Hosp. Med. Sch., London.] Spanish summary.

The apparatus used is described and illustrated. Data tabulated for 24 infants are age, sex, weight, minute volume, minute loss of water, minimum loss of water per day and per kg. bodyweight, and percentage saturation of the expired air, assumed to be at a temperature of 37°C.

Pulmonary water loss was proportional to minute volume. There was an approximately linear relationship between minimum daily water loss from the lungs and bodyweight. For the 24 infants, minimum daily loss per kg. bodyweight ranged from 6.4 to 12.3, average 8.6 g.

LIVIERATO, S., DANOFULOS, E. and MARATOS, K. The functional control of the RES in patients with undernutrition. *Acta med. scand.*, 1954, 148, 469-476. [I. Med. Clin., Univ. Athens.]

Blood alcohol curves were studied in 23 undernourished patients after administration of 0.6 ml. ethanol per kg. bodyweight by mouth as a 10 per cent. solution. In another 17 patients with oedema the alcohol content of the oedema fluid was also studied.

In 4 normal subjects the highest point of the

N.A. and R., January 1955

alcohol curve did not exceed 0.65 per thousand, and almost the whole amount of alcohol had disappeared after 4 hr. In the 23 patients with little or no oedema the height of the curve increased with the severity of the undernutrition; in the 3 examples given the peaks were 1.6, 1.55 and 1.1 per thousand, and appreciable levels of alcohol were still present after 4 hr. The ability to metabolise alcohol was still further impaired in the oedematous patients.

It is considered that the results indicate functional impairment of the reticulo-endothelial system in undernutrition. Alcohol should not be given to such patients as a source of energy.

D. Duncan.

911

JOHANNESMEIER, K., REDETZKI, H. and PFLEIDERER, G. Zur Frage der Beschleunigung des Blutalkoholabbaus. [The problem of accelerating alcohol breakdown in the blood. [*Klin. Wochenschr.*, 1954, 32, 560-563. [Inst. Gerichtl. Med., Univ. Hamburg.]

Alcohol and pyruvic acid were estimated in the blood of 2 sheep at intervals after administration of 40 ml. of 96 per cent. ethanol, alone or with 25 g. fructose or 25 g. glucose, or 3.68 or 2.80 g. pyruvic acid, or 300 mg. diphosphopyridine nucleotide. The supplements were given by intravenous injection simultaneously with the alcohol or at intervals up to 65 min. after it. They had no effect in accelerating the disappearance of the alcohol from the blood.

Oral administration of fructose 2 hr. after alcohol to 4 human subjects caused vomiting in 2 and did not affect the level of alcohol in the blood of the other 2.

In the human subjects and the sheep, administration of fructose or glucose alone caused the pyruvic acid value in the blood to rise to about the same extent.—E. M. Hume.

912

MARDONES, J., SEGOVIA, N., ALCAINO, F. and HEDERRA, A. Effect of synthetic thioctic or alpha lipoic acid on the voluntary alcohol intake of rats. *Science*, 1954, 119, 735-736. [Lab. Nutric., Inst. Educación Física, Univ. Chile, Santiago.]

Rats received for at least 90 days a diet with 11 pure vitamins as the only source of the vitamin B complex, and were allowed alcohol at will until their intake was fairly stable. When these rats were given α -lipoic or thioctic acid for from 4 to 10 days, in total doses of 62.5, 125 or 750 μ g. per 100 g. bodyweight by mouth or the smallest dose subcutaneously, alcohol intake subsequently decreased slightly but significantly. The decrease was less consistent than that produced by 2 g. dried liver per 100 g. bodyweight daily for 10 days.

Vol. 25, No. 1

This supplement represents 40 to 80 μ g. thioctic or α -lipoic acid, and these substances therefore are not wholly responsible for the effect of liver in decreasing alcohol consumption.—D. Duncan.

913

DAUGHADAY, W. H. and LARNER, J. (with HOUGHTON, E.) The renal excretion of inositol by normal and diabetic rats. *J. Clin. Invest.*, 1954, 33, 1075-1080. [Dept. Med., Sch. Med., Washington Univ., St. Louis, Mo.]

The excretion of inositol was studied in normal and partly depancreatized rats on low, medium and high inositol intakes and in alloxan-diabetic rats on low and high inositol intakes. Absorption and renal clearance of inositol were also studied.

Normal rats excreted little inositol even when the intake was 1623 mg. in 24 hr. Partly depancreatized rats excreted much more at all 3 levels of intake, but insulin treatment reduced inositol excretion almost to normal, even when the insulin treatment was accompanied by salt diuresis. Alloxan-diabetic rats also excreted large proportions of the inositol intake.

Absorption of inositol was more rapid in diabetic than in normal rats, 46 per cent. in 6 hr. compared with 26 per cent. The urinary clearance of inositol in diabetic rats was at least 10 times the normal. When normal rats received glucose intravenously the clearance of inositol rose to the range found in diabetes.

It is concluded that the increased excretion of inositol in diabetes can be attributed to the increased renal clearance produced by glycosuria.

D. Duncan.

914

ALSTRÖM, I. The effect of inositol on the rate of phosphorus metabolism in the liver of rats. *Acta med. scand.*, 1954, 148, 433-438. [Dept. Metabol. Res., Wenner-Gren's Inst., Stockholm.]

Addition of 200 mg. inositol to 100 g. of a semi-synthetic diet free from inositol had no effect on the rate of growth of young rats in a 30-day experiment. This indicates that the supply of inositol was adequate, probably because of formation of inositol by the bacterial flora. In rats starved for 72 hr. after being given a complete diet, subsequent addition of 200 mg. inositol to 100 g. of the complete diet caused a decrease in the rate of P metabolism in the liver, as measured with 32 P.—M. B. Richards.

HOLLMANN, S. Über das Schicksal der Glucuronsäure im tierischen Organismus. 2. Die Glucuronsäure-Resorption aus dem Darm. [Fate of glucuronic acid in the animal body. 2. Absorption of glucuronic acid from

intestine.] 3. Vergleichende Untersuchungen über den Glucuronsäure-Abbau in verschiedenen Säugetiergeweben. [3. Comparative studies of the breakdown of glucuronic acid in different mammalian tissues.] *Hoppe-Seyler's Ztschr.*, 1954, 297, 74-82; 83-91. [Physiol.-Chem. Inst., Univ. Göttingen.]

2. Glucuronic acid absorption from the intestine was studied in man, dog, rabbit and guineapig, to find whether incomplete absorption after oral intake could be the cause of results previously reported (*Hoppe-Seyler's Ztschr.*, 1952, 290, 91), in which urinary excretion of glucuronic acid was much less after ingestion than after intravenous injection of 3 g. glucuronic acid lactone. These experiments showed that man could absorb at least 7-5 g. of the lactone, and up to this level the lower excretion after oral ingestion was due to breakdown of the acid in the liver. With 3 g. lactone the absorption losses were at most 2 per cent. In the rabbit urinary excretion of glucuronic acid was lower after intraperitoneal than after intravenous or subcutaneous injection, since part of it was broken down in traversing the liver. In the dog with an Eck fistula the diminished excretion after oral intake was partly due to breakdown in the liver, and partly to incomplete absorption from the intestine. The glucuronic acid deficit after intravenous injection might be due mainly to breakdown in extra-hepatic tissues, as indicated in the following paper.

3. The relative activity of different tissues in the breakdown of glucuronic acid was estimated by measuring the increase in the oxygen consumption of guineapig tissues caused by 0.005 M K glucuronate in phosphate buffer of pH 7.0. The greatest increase was in the liver, followed in order by skeletal muscle, kidney, spleen, brain, lung and

heart. Guineapig and dog tissues were used to estimate the activity as measured by the disappearance of glucuronate when broths of the tissues were treated with K glucuronate at 39° C. in the phosphate buffer solution. Again the liver showed the highest activity, followed by kidney, muscle, brain, lung, heart and spleen.

METABOLISM OF CELLS, TISSUES, ETC.

GENERAL PHYSIOLOGY

918

CLARK, R. T. (JR.), CHINN, H. I., ELLIS, J. P. (JR.), PAWEL, N. E. R. and CRISCUOLO, D. Tissue respiratory studies during altitude and cold exposure. *Amer. J. Physiol.*, 1954, 177, 207-210. [U.S. Air Force Sch. Aviation Med., Randolph Field, Tex.]

The oxygen consumption of liver slices from 26 male rats which had been maintained at successively lowered barometric pressures, reaching a simulated altitude of 18,000 ft. after 30 days, was estimated in 100 per cent. oxygen with β -glycerophosphate in Locke's solution; 20 rats acted as controls. In a second experiment the oxygen consumption of liver slices was estimated under 100 per cent. and reduced oxygen atmospheres for

6 adult rats maintained at 18,000 ft. for 35 to 38 days and exercised for 1 hr. daily on a treadmill, for 13 control rats similarly exercised at ground level and 9 rats maintained at altitude without exercise. In a third experiment the oxygen consumption of liver slices was estimated for 8 male rats kept at 4° C. for 10 weeks; 7 animals acted as controls.

A slight, but significant, decrease occurred in the oxygen consumption of liver slices from the rats chronically exposed to altitude and there was a much higher oxygen consumption in liver slices from rats exposed to cold. Liver slices from exercised rats exposed to altitude had a significantly lower oxygen consumption than had slices from the control animals similarly exercised at ground level; no significant difference was noted

N.A. and R., January 1955

when the liver slice was allowed to respire in air or 12-5 per cent. oxygen. The cyclophorase activity of liver and kidney of rats exposed to cold and of liver, kidney, diaphragm, heart, soleus muscle, gastrocnemius muscle and brain of rats exposed to altitude was also estimated; only the activity of diaphragm was significantly higher after exposure to altitude, but considerable variations in cyclophorase activity were found among different groups of animals.—G. F. Garton.

919

WEISS, A. K. Adaptation of rats to cold air and effects on tissue oxygen consumptions. *Amer. J. Physiol.*, 1954, 177, 201-206. [Dept. Physiol., Sch. Med. Dent., Univ. Rochester, N.Y.]

After groups of rats aged 6 weeks or 6 months had been in an environment at $5^{\circ} \pm 1^{\circ}$ C. for 10 or 26 days with food to appetite the oxygen consumption of slices of diaphragm, liver, kidney, heart and brain cortex was estimated by the Warburg method; littermates served as controls.

With the exception of brain cortex, all the tissues from 6-week-old rats showed an increase in oxygen consumption after exposure to cold; liver showed the greatest percentage increase and kidney the least. The tissues of 6-month-old rats showed no increase in oxygen consumption on exposure to cold for either 10 or 26 days; occasionally liver tissue showed a significant increase. The oxygen consumption rates at 37° C. were about double those at 24° C.; changes which were interpreted as having a significance at 37° rarely had as great a significance at 24° and, usually, no significance. When 6-week-old rats, previously exposed to cold for 10 days, were returned to room temperature for 2 days all the tissue oxygen consumptions studied remained high. When weanling rats were exposed to $5^{\circ} \pm 1^{\circ}$ C. most died, but when they were exposed to $12^{\circ} \pm 2^{\circ}$ C. for 5 days no significant increase in tissue oxygen consumption was found. The adrenals of all the rats exposed to cold were enlarged; the extent of the hypertrophy was correlated with the severity of the cold. In general the tissues from young rats respired at a greater rate than those from older rats and tissues which did not alter their oxygen consumption in response to cold did not show a modification with age.—G. F. Garton.

RENOLD, A. E., HASTINGS, A. B. and NESBETT, F. B. Studies on carbohydrate metabolism in rat liver slices. 3. Utilization of glucose and fructose by liver from normal and diabetic animals. *J. Biol. Chem.*, 1954, 209, 687-696. [Dept. Biol. Chem., Harvard Med. Sch., Boston, Mass.]

Liver slices from normal and diabetic rats were incubated in a cationic medium with glucose or fructose uniformly labelled with ^{14}C in all carbon atoms. In the livers from diabetic rats glucose uptake and glycogen deposition from glucose were about 50 and 98 per cent. below normal, respectively, and glucose output was increased by 50 per cent. Fructose utilisation was nearly normal and there was significant formation of glycogen, though only 1/4 to 1/9 of that in normal liver. Glycogen formation from glucose and from fructose in normal liver slices was almost identical.

With both glucose and fructose, only one labelled, as substrates and formation of the osazone at the end of incubation, the comparative utilisation of the hexoses was studied. A minimum and maximum value for total glucose phosphorylation was calculated from this, and in diabetic liver slices it was between 1/4 and 1/10 of normal. Fructose utilisation was normal, but 70 per cent. was converted into glucose as compared with 32 per cent. in normal liver, which indicated the increased tendency to gluconeogenesis in diabetic liver.

CHARI, A. and WERTHEIMER, E. The effect of ketone bodies on the carbohydrate metabolism of rat diaphragm. *Biochem. J.*, 1954, **57**, 443-449. [Dept. Biochem., Hebrew Univ., Hadassah Med. Sch., Jerusalem.]

Diaphragms from rats weighing from 80 to 120 g. were incubated in phosphate-buffered saline medium. When the medium contained 0.1 per cent. glucose, addition of 0.1 per cent. acetoacetate decreased glycogen formation, 0.25 per cent. β -hydroxybutyrate increased it and 0.05 per cent. acetone or 0.1 per cent. β -hydroxybutyrate had no effect. Similar effects were found with liver slices. In the absence of glucose 0.1 per cent. acetoacetate did not affect the rate of glycogen breakdown, but 0.1 per cent. β -hydroxybutyrate or 0.05 per cent. acetone decreased it. The decrease in glycogen formation in the presence of acetoacetate depended on the relative concentrations of glucose and acetoacetate present. In the presence of acetoacetate both glucose and oxygen were utilised more rapidly. The increase in glycogen formation occurring in the presence of 0.1 unit of insulin was inhibited by acetoacetate, but not by the other ketone bodies studied.

The presence of 0.1 per cent. β -hydroxybutyrate decreased the effect of the acetoacetate. The effect of 0.001 *M* methylene blue was similar to that of acetoacetate and the two were not synergistic. The effect of acetoacetate was absent with diaphragms from diabetic rats or from rats fasted for 5 to 7 days, but was present with diaphragms from rats fed on a high-fat diet for 12 days. Injection of acetoacetate within 6 hr. before the rats were killed decreased glycogen formation *in vitro* and also depressed the blood sugar level *in vivo*. Injection of β -hydroxybutyrate cancelled the effect of the acetoacetate.

It is concluded that acetoacetate, at concentrations comparable to those found in diabetic coma, is the only ketone body decreasing glycogen formation.—D. Duncan.

COCHRAN, K. W. and DuBOIS, K. P. The influence of certain steroids on the oxidation of α -keto acids. *Endocrinology*, 1954, **55**, 10-20. [U.S. Air Force Radiation Lab., Chicago, Ill.]

The synthesis of citrate from pyruvate and fumarate by liver homogenates from rats was inhibited *in vitro* by testosterone, deoxycorticosterone, ethinyl oestradiol, progesterone and diethylstilboestrol; steroids which were relatively ineffective as inhibitors were oestradiol, oestrone, pregnenolone, methyl androstenediol, cortisone, cholesterol and ouabain. The synthesis of acetoacetate from pyruvate was greatly inhibited by testosterone, deoxycorticosterone, progesterone and diethylstilboestrol. Steroids which inhibited the synthesis of citrate and acetoacetate also inhibited the oxidation *in vitro* of α -ketoglutarate, but not that of succinate.—G. F. Garton.

927

ZAMECNIK, P. C. and KELLER, E. B. Relation between phosphate energy donors and incorporation of labeled amino acids into proteins. *J. Biol. Chem.*, 1954, **209**, 337-354. [Med. Labs., Collis P. Huntington Mem. Hosp., Harvard Univ., Massachusetts Gen. Hosp., Boston.]

A preparation that would incorporate leucine- ^{14}C into protein anaerobically was made by partly homogenising rat liver and centrifuging at 5000 *g* to remove mitochondria. Incorporation was greatly stimulated by hexosediphosphate with nicotinamide or by phosphocreatine, phosphoryl pyruvate or 3-phosphoglycerate, but not by adenosine triphosphate (ATP) or coenzyme A. A similar preparation after treatment with activated charcoal needed both ATP and one of the other substances. Most of the incorporation was into the protein of the microsome-rich fraction obtained by centrifuging at 105,000 *g*. The essential components of the incorporating system were this microsome-rich fraction, a soluble, heat-labile, non-dialysable fraction, an ATP-generating system and the amino-acid. Arsenate, dinitrophenol or ethionine caused little inhibition of the incorporation itself, though iodoacetate, ribonuclease or deoxycholate inhibited strongly. When several amino-acids were added together there did not seem to be competition between them. The reaction was specific for natural L-amino-acids. Degradation of the labelled protein released labelled leucine at about the same rate as unlabelled leucine. A radio-active peptide has been isolated from a partial hydrolysate and is being further studied.—C. Warner.

ATEN, A. H. W. (Jr.), COUSSINS, R., MASSART, L. and PETERS, G. Incorporation of $\text{Na}_2^{35}\text{O}_4$ and Na_2^{32}S in milkproteins by the perfused cow's udder. *Arch. internat. Pharmacodyn.*, 1953-54, **96**, 356-364. [Lab. Nuclear Phys., Amsterdam.] French summary.

N.A. and R., January 1955

Both halves of the excised udder of a lactating cow were perfused separately for 2 hr. with heparinised, oxygenated blood containing $1 \mu\text{C. Na}_2^{35}\text{SO}_4$. Blood and milk samples were collected.

The total activity of the blood and of the inorganic S of the blood were much less than before perfusion; the protein activity remained about the same. Casein and lactalbumin from milk had a low but definite activity, much higher than that from incubation with $\text{Na}_2^{35}\text{SO}_4$ *in vitro*.

$\text{Na}_2^{35}\text{SO}_4$ continuously added to the perfusion blood produced only slight radio-activity in the casein and albumin fractions. The activity disappeared on washing with inactive Na_2S solution. Incubation *in vitro* with Na_2^{35}S yielded strongly active proteins in milk and blood. As washing with inactive Na_2SO_4 and finally with Na_2S greatly diminished activity, a large quantity of Na_2S was thought to be bound by chemical reaction or by absorption. Incubation *in vitro* with $\text{Na}_2^{35}\text{SO}_4$ produced only slight activity in blood and milk proteins.—A. Hepburn.

929

SHMERLING, ZH. G. and MOGILEVSKAYA, Z. G. Obmen glyutamina i aspargina v platzente i embriionakh krysi i krolikov. [Metabolism of glutamine and asparagine in the placenta and in embryo rats and rabbits.] *Biokhimiya*, 1954, 19, 30-35. [Inst. Med. Biol. Khim., Akad. Med. Nauk SSSR, Moscow.]

Metabolism of glutamine and asparagine in tissue slices and homogenates from embryos and placenta of rat and rabbit was studied at different stages of foetal development. Glutamine was present in placental and embryonic tissues of the rat at all stages, the amount increasing with growth. Synthesis of glutamine from glutamic acid and ammonia was observed in rabbit placental slices, but could not be demonstrated in either slices or homogenates of rat placenta. *In vivo*, however, formation of glutamine could be demonstrated in these tissues after injection of ammonium salts.

Glutaminase was found to be present in both rat and rabbit placenta, but asparaginase was absent from rat placenta although it appeared in embryonic tissues of both rat and rabbit towards the end of pregnancy.—D. W. Taylor.

930

JOHNSON, R. M., LEVIN, E. and ALBERT, S. Lipide metabolism during cell division. *Arch. Biochem. Biophys.*, 1954, 51, 170-175. [Richard Cohn Radiobiol. Lab., Detroit Inst. Cancer Res., Mich.]

Adult rats were each given a single subcutaneous injection of $45 \mu\text{C. NaH}_2^{32}\text{PO}_4$ per g. bodyweight either 1, 3 or 18 days after partial removal of the

liver and were killed 1 hr. later. The animals killed 3 days after operation were given also 0.03 mg. colchicine per 100 g. bodyweight by subcutaneous injection. Liver lipids were extracted.

In the regenerating liver tissue maximum ^{32}P activity in the phospholipin fractions was in rats killed at 3 days; the administration of colchicine caused an increase of about 50 per cent. in the incorporation of ^{32}P into the cephalins and slight increases in the incorporation of ^{32}P into the other 2 fractions. Since colchicine, a metaphase inhibitor, did not abolish the uptake of ^{32}P into phospholipins it is suggested that the high ^{32}P uptake is associated with either interphase or prophase, but not with anaphase or telophase. Coincident with the period of hypertrophy on the day after operation in the regenerating livers there was an increase in the concentration of trienoic fatty acids and a decrease in tetraenoic acids. Three days after operation, when there was maximum mitotic activity, there was a considerable increase in the concentration of dioenoic acid; the inhibition of mitosis in metaphase with colchicine did not affect the level of dioenoic fatty acids.—G. A. Garton.

931

HATZIOLOS, B. C., YAMIN-SMITH, M. L. and SHAW, J. C. Histochemical studies of fat metabolism in mammary glands of lactating cows. *J. Dairy Sci.*, 1954, 37, 924-931. [Dairy Dept., Maryland Agric. Exp. Stat., College Park.]

Active mammary tissue from 3 dairy cows in mid-lactation was excised immediately after the animals were stunned and also 0.5, 1, 2 and 4 hr. *post mortem*. After fixing in formalin the tissue was stained with fat stains.

All the fatty droplets in the secretory cells appeared to consist of neutral fat; no free fatty acid was detected. It is concluded that, if free fatty acids are formed in the secretory cells as a result of the hydrolysis of blood fat, conversion to glycerides must be very rapid.—G. A. Garton.

932

JEDEIKIN, L. A. and WEINHOUSE, S. Studies of the incorporation of palmitate-1- C^{14} into tissue lipides *in vitro*. *Arch. Biochem. Biophys.*, 1954, 50, 134-147. [Lankenau Hosp. Res. Inst., Philadelphia, Pa.]

Palmitate-1- ^{14}C was incubated in a Warburg apparatus with tissue slices or tissue homogenates obtained from fasting and normally fed rats, usually for 3 hr. at 38°C ., under oxygen or nitrogen. Phospholipins were then isolated by acetone precipitation and their constituent fatty acids were isolated for radio-active assay. Fatty acids were also isolated from the P-free lipids and were assumed to have been derived mainly from glyceride fat.

All the tissues examined were able to oxidize palmitate, the most active being kidney, heart, spleen and liver; incorporation of palmitate was generally greater in non-phospholipins than in phospholipins and occurred in all except adipose tissue. The incorporation of the labelled acid was significantly higher in tissues from fed than from fasted rats. The uptake of palmitate into phospholipins was influenced positively by the presence of oxygen and was impaired by the presence of respiration inhibitors, *e.g.*, cyanide, and phosphorylation inhibitors, *e.g.*, azide and dinitrophenol. Similar effects were not observed on the incorporation of palmitate into non-phospholipins.

Coenzyme A was found to stimulate the incorporation of palmitate into phospholipins in pigeon liver preparations; a similar effect could not be consistently demonstrated in rat liver.

It is suggested that the fatty acid ester bonds of phospholipins are formed by stepwise transesterification between acyl coenzyme A and either glycerophosphate or glycerophosphorylcholine.

LYON, I. and GEYER, R. P. **Fatty acid metabolism and hepatic lipogenesis.** *J. Biol. Chem.*, 1954, 203, 529-536. [Dept. Nutrit., Harvard Sch. Pub. Health, Boston, Mass.]

Octanoate- 1^{14}C was incubated with rat liver slices as described earlier (Abst. 2395, Vol. 20) to study its conversion to CO_2 , acetoacetate, cholesterol and long- and short-chain fatty acids in the presence of pyruvate, succinate, or fumarate, alone or in combination with malonate.

Long-chain fatty acid synthesis was inversely related to the amount of acetoacetate formed. Malonate alone did not affect the incorporation of octanoate into long-chain fatty acids, though less $^{14}\text{CO}_2$ was formed; the ^{14}C content of the resulting acetoacetate and short-chain acids increased. The addition of malonate to the incubation medium containing pyruvate, succinate or fumarate increased long-chain fatty acid synthesis and decreased conversion of octanoate to acetoacetate and short-chain fatty acids.—G. A. Garton.

ANNISON, E. F. and PENNINGTON, R. J. **The metabolism of short-chain fatty acids in the sheep. 3. Formic, *n*-valeric and some branched-chain acids.** *Biochem. J.*, 1954, 57, 685-692. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]

Rumen epithelial tissue, liver and kidney slices were incubated with isobutyrate, *n*-valerate, isovalerate and α -methylbutyrate, with techniques already described (Absts. 2562, Vol. 22 and 3434, Vol. 24). All the acids were metabolised by rumen epithelial tissue: small amounts of acetate and propionate were formed from isobutyrate, *n*-valerate and α -methylbutyrate, and isovalerate gave rise to acetate and possibly to isobutyrate. The valerate isomers increased formation of ketone bodies. In the absence of CO_2 from the gas phase of the incubation mixture, isovalerate inhibited respiration of rumen epithelium. Liver and kidney slices also broke down the acids to shorter-chain products.

The absorption of these salts from the rumen was studied in a ewe with the rumen tied off; blood samples for analysis were withdrawn from the carotid artery and the posterior rumen vein and absorption of all 4 acids was demonstrated.

Chromatographic evidence revealed the presence of formate in sheep blood. Liver slices utilised formate; kidney, which utilised the other short-chain acids more rapidly than did liver, was less active, and rumen epithelium did not metabolise formate.—G. A. Garton.

937

DAVISON, J. P., SIMONSON, C. and CORNATZER, W. E. **Effect of coenzyme A on phospholipide synthesis in rat liver slices.** *Biochim. biophys. Acta*, 1954, 15, 141-142. [Dept. Biochem., Med. Sch., Univ. N. Dakota, Grand Forks.]

Liver slices from rats were incubated in Krebs Ringer phosphate buffer, pH 7.3, for 4 hr. at 37°C . in the presence of approximately $2\ \mu\text{Ci. }^{32}\text{P}$, in a Warburg apparatus under an atmosphere of 95 per cent. oxygen and 5 per cent. CO_2 . Coenzyme A (CoA), adenylic acid, ADP, ATP, succinate and cysteine were added singly or in combinations. The metabolic activity of the slices was terminated by the addition of trichloroacetic acid (TCA) and the radio-activity and P content of the lipid and TCA fractions were estimated.

CoA at a concentration of $7.7 \times 10^{-4}\text{ M}$ caused a decrease of 69.4 per cent. in the incorporation of phosphate into phospholipins, but with a lower concentration, $1.54 \times 10^{-4}\text{ M}$, stimulation of synthesis resulted. Adenylic acid, ADP or ATP with CoA at the lower concentration decreased the rate of phospholipin synthesis. Cysteine with CoA inhibited phospholipin formation; succinate had little effect.—G. A. Garton.

WERTHESSEN, N. T., MILCH, L. J., REDMOND, R. F., SMITH, L. L. and SMITH, E. C. Biosynthesis and concentration of cholesterol by the intact surviving bovine aorta *in vitro*. *Amer. J. Physiol.*, 1954, 178, 23-29. [Dept. Physiol., Southwest Found. Res. Educat., San Antonio, Tex.]

Aortas removed from bull calves aged between 3 and 14 days were maintained *in vitro* as described by Werthessen and Schwenk (Title 2046, Vol. 23). The perfusion fluid contained sodium acetate-1-¹⁴C. Samples of the aortas were analysed for cholesterol before and at intervals after perfusion; glucose consumption from the perfusing medium was estimated.

Cholesterol was concentrated by the isolated aortas; the increase in concentration was related to the utilisation of glucose. Radio-active cholesterol digitonide was isolated, showing that cholesterol had been formed.

Cholesterol elaborated by the aorta itself may prove to be as important in the genesis of atherosclerosis as cholesterol taken up directly from the bloodstream.—G. A. Garton.

ALLARD, C. and CANTERO, A. Adenosinetriphosphatase study during rat liver damage. 2. ATP-ase activity of rat liver during 4-dimethylaminoazobenzene carcinogenesis. *Rev. canad. Biol.*, 1953, 12, 35-39. [Cancer Inst., Montreal.] French summary.

Rats weighing from 150 to 200 g. were maintained for from 15 to 90 days on a low-protein, semi-synthetic diet with or without 0.06 per cent. 4-dimethylaminoazobenzene. Adenosinetriphosphatase was estimated in homogenates of the liver and in nuclear, mitochondrial and supernatant fractions from the homogenates. The enzyme was low only in the mitochondrial fraction, which seemed to be due to a decrease in the number of mitochondria rather than to a decrease in the enzyme activity of individual mitochondria.

No evidence was thus obtained of any relation between adenosinetriphosphatase activity of the liver and the process of carcinogenesis.

NELSON, D., SZANTO, P. B., WILLHELM, R. and IVY, A. C. Hepatic tumors in rats following the prolonged ingestion of milk and egg yolk. *Cancer Res.*, 1954, 14, 441-444. [Dept. Clin. Sci., Coll. Med., Univ. Illinois, Chicago.]

Ten male and 10 female rats were given a diet designed to produce arteriosclerosis, consisting of 5 per cent. powdered egg yolk in whole milk. The mixture was homogenised in a Waring Blender, but the yolk rose to the top during the day and so the diet as consumed contained more than 5 per cent. egg yolk. Initially the males were 10 to 23 weeks and the females 15 to 19 weeks old.

Moribund animals were killed and all the survivors were killed at the end of 2 years.

No rat which survived less than 1½ years had a hepatic tumour, but of those which lived more than 1½ years 3 of the 4 males and 3 of the 6 females developed hepatic tumours. The average age of these 6 rats was 111 weeks, and all received the yolk diet for at least 78 weeks. In the stock colony among 25 rats of comparable age there was no hepatic tumour.

In all the rats with tumours the liver was enlarged, with fatty changes and focal necrosis, but no cirrhosis. Tumour nodules replaced the liver parenchyma, and appeared to be liver-cell hepatomas. The genesis of the tumours is discussed.

D. Duncan.

947

DUNNING, W. F. and CURTIS, M. R. Further studies on the relation of dietary tryptophan to the induction of neoplasms in rats. *Cancer Res.*, 1954, 14, 299-302. [Dept. Microbiol., Univ. Miami, Coral Gables, Fla.]

This paper extends the studies reported in Absts. 2410 and 3933, Vol. 20, to a lower, slightly inadequate concentration of tryptophan. Diethylstilboestrol-treated rats on a diet containing 26 per cent. tryptophan-free casein hydrolysate supplemented with 0.14 per cent. DL-tryptophan lost less weight and showed a greater increase in pituitary weight than rats on a similar but unsupplemented diet; they survived longer and developed more mammary cancer with longer average latent period, in contrast to the decreased latent period previously found when 1.4 per cent. tryptophan was used.

Among rats given 0.06 per cent. 2-acetylaminofluorene to induce liver cancer, those given tryptophan developed more neoplasms and survived for a shorter time. In contrast to the previous experiments, when 1.4 or 4.3 per cent. tryptophan was given and all other conditions were the same, no bladder tumour was found.

It is concluded that a partial chronic deficiency of dietary tryptophan did not protect against induced liver or mammary gland neoplasms.

LE BRETON, E. Role déterminant d'un facteur alimentaire simple dans l'obtention certaine du cancer du foie chez le rat Wistar ingérant un cancerigène (*p*-diméthylaminoazobenzène.) [Dominant role of a simple food factor in the certain production of liver cancer in the Wistar rat consuming a carcinogen (*p*-diméthylaminoazobenzène).] *C.R. Acad. Sci.*, 1954, 238, 2446-2448.

It was earlier shown (Abst. 2464, Vol. 22) that on a balanced diet containing 5 per cent. cholesterol, *p*-diméthylaminoazobenzène (butter yellow) produced no liver cancer in rats even after 30 to 36 months of ingestion. The diet contained, per 100 g.: casein 17, lactalbumin 3, sucrose and lactose 60, purified lard 10, brewer's yeast 2.5, salt mixture 5, agar 2.5, with choline 0.2, riboflavin 0.002, all the other B vitamins and vitamins A, D and E, and butter yellow 0.06 g. To 100 g. diet was added 5 g. cholesterol.

In 100 rats on this diet no liver cancer developed. When 10 per cent. sucrose replaced the lard or when choline was omitted, the incidence of liver tumours was 100 per cent.

This is the first report that by modification of a single dietary factor (the choline:glyceride ratio) it is possible to obtain liver cancer with certainty.

BARVICK, L. and GOODSON, L. H. Effects of combined chemotherapy on Sarcoma 180, with special reference to food intake, body-weight

changes, and survival time. *J. Nat. Cancer Inst.*, 1954, 15, 177-189. [Chem. Res. Div., Midwest Res. Inst., Kansas City, Mo.]

Mice bearing transplants of sarcoma 180 received singly or in combination amethopterin, N,N-bis(2-chloroethyl)-aniline, triethylene melamine and erythromycin, all by intraperitoneal injection. Singly all were toxic, and effects on the host could not be separated from those on the tumours. Amethopterin with triethylene melamine or with N,N-bis(2-chloroethyl)-aniline, and the latter with erythromycin, were effective in increasing the time of survival, in spite of losses in bodyweight.

Experiments with food restriction and starvation, designed to separate the effects of these agents on the nutritional state of the mice from effects on the tumour, were inconclusive.—D. Duncan.

HERDAN, G. The relation between birth weight and subsequent weight in childhood. *Arch. Dis. Childhood*, 1954, 29, 220-223. [Dept. Prevent. Med., Univ. Bristol.]

Examination of published data and the author's Bristol data on the weights of children at birth, 3 months and 6 months showed that the positive correlation between birthweight and subsequent weight decreased with age. In the Bristol study average weight gain at 3 and 6 months was inversely related to birthweight. These results are discussed.—F. C. Aitken.

956

THOMSON, J. Birth weight and weight increment in the first year. *Med. Officer*, 1954, 92, 75-76. [Dept. Child Life, Univ. Edinburgh.]

Vol. 25, No. 1

A cross-sectional study was made of the weights at 2, 4, 12, 26, 40 and 52 weeks of healthy single first-born boys and girls born in Edinburgh Royal Infirmary; most groups were of 100 or more.

Boys gained more weight than girls, especially in the first 12 weeks. Most of the correlations between birthweight and weight increment were small and negative and none was significant after 4 weeks for boys and 12 weeks for girls, in agreement with the author's other findings (Abst. 4966, Vol. 24) and those of Parfit (Abst. 2424, Vol. 21).

PHILLIPS, H. T. The seasonal growth of nursery-school children in relation to social and ethnic factors. *S. African J. Clin. Sci.*, 1954, 5, 82-96. [Inst. Family Health, Merebank, Natal.]

The weights and heights of 3 groups of South African nursery schoolchildren, lower income white, upper income white and Bantu, were taken regularly for 15 years and the results are analysed statistically to investigate the seasonal variations in increases.

In weight gains in the lower income white group there was no difference with age except for 3-year-old girls who gained significantly more in summer than did 4-year-old girls. There was no significant difference with sex. White children in the lower income group and the Bantu children had gains significantly greater in autumn and winter than in spring and summer; upper income group boys gained significantly more in winter and in summer than in spring, but girls of this group showed no significant seasonal change. In autumn lower income group boys gained significantly more than

upper income boys; Bantu girls gained in winter significantly more and in summer significantly less than did white girls.

Seasonal growth in height was studied only in the lower income white group and in Bantu children. There was no significant seasonal difference for the lower income children, but the growth of the Bantu children was significantly better in spring and summer than in autumn and winter.

MULCOCK, D. A short study of the onset of puberty in boys. *Med. Officer*, 1954, 91, 247-249.

Height, weight, bipelvic diameter, and criteria of development were recorded at quarterly examinations of 100 boys between 10 and 15 years randomly selected from 257 pupils of a preparatory school for the well-to-do in Leeds. The results are compared with those of Ellis (Abst. 2264, Vol. 17) and several U.S. workers.

In each age group the more mature were heavier and taller. The mean age of appearance of pubic hair was 12 years 3 months, which is between 6 and 12 months earlier than that quoted in the literature. Over three-quarters of the boys belonged to the Registrar-General's classes 1 and 2, but even so puberty was earlier in the most prosperous of 3 groups. In the age group 12 to 13, 65 per cent. were judged pubescent, 5 per cent. adolescent and 30 per cent. pre-pubescent. For 30 Anglicised Jewish boys considered separately, the average age of onset of puberty was about a year lower than in the whole group of 100, of which they formed part.—W. M. Deans.

MURO, A., ACEÑA, A. and VIVANCO, F. Patrones de crecimiento de niños normales españoles. [Growth patterns of normal Spanish children.] *Rev. clín. española*, 1954, 53, 360-363. [Inst. Nac. Hig. Aliment. Nutric., Madrid.] English, German and French summaries.

Heights and weights are tabulated according to age for 4940 healthy boys, from 6 to 18 years old, at 2 schools in Madrid. The means are compared with those of Wetzel (Abst. 1498, Vol. 11) and Suárez and Teixeira (*Proc. VIII Congreso Nac. Pediat., Barcelona*, 1952). It is concluded that the data may be regarded as representative of the growth of normal Spanish boys.—D. Duncan.

960

MURO, A. and ACEÑA, A. Nuevo metodo grafico para la determinacion de la edad de crecimiento infantil. Gegonia auxologica Muro-Aceña. [New graphic method of determining the age of growth of infants. Gegonia auxologica of Muro and Aceña.] *Rev. clín.*

española, 1954, 53, 364-366. English, German and French summaries.

From the data in the preceding paper the authors have prepared a new grid system for assessing growth according to age, height and weight. The graph is given the name "gegonia auxologica", and is considered useful with Spanish children.—D. Duncan.

961

LELONG, M., JOSEPH, R., CANLOBE, P. and SCHOLLER, R. Une nouvelle méthode de représentation graphique de la croissance. [A new method of representing growth graphically.] *Presse méd.*, 1954, 62, 701-704. [Centre Endocrinol. Infantile, Clin. Pédiat., Hôp. Saint-Vincent-de-Paul, Paris.]

The measurements recorded are, in addition to age, weight, standing height, finger-tip breadth, height from upper edge of pubic symphysis to ground, girth at the xiphisternum and umbilicus (as a measure of state of nutrition) and bi-lumeral and bi-trochanteric diameters (as a measure of sexual maturity). Height is the reference measurement and the others are compared with "normal" measurements for the height of the child examined. Its use as described is clinical. Examples are for children with myxoedema, precocious sexual development, pituitary nanism and genetically slow growth.—I. Leitch.

962

GARCIA ALVAREZ, M. R. Desarrollo físico de un grupo de niños de una zona rural. [Physical development of a group of children in a rural area.] *Medicamenta*, 1954, 22, 65-72. [Inst. Laboral, Ribadavia, Orense.]

The subjects were 79 pupils of the Centro Laboral de Ribadavia, aged from 10 to 18 years. They were grouped by age and variations in weight, height and thoracic circumference were studied [the groups aged 15, 17 and 18 consisted of 1, 1 and 2 subjects].

Although the children came from poor agricultural families their development was similar to that of other Spanish children of good economic position and well nourished American and Central European children (Baldwin and Wood, and von Pirquet), when compared by Wetzel's methods. It is considered that in contrast to low-income groups in Spanish towns, the country children are well fed.—D. Duncan.

963

ABRAMSON, E. and ERNEST, E. Height and weight of schoolboys at a Stockholm secondary school, 1950, and a comparison with some earlier investigations. *Acta paediat.*, 1954, 43, 235-246. [State Inst. Pub. Health, Tomtebodavägen, Sweden.] French, German and Spanish summaries.

N.A. and R., January 1955

Mean heights and weights at yearly intervals with standard deviations are tabulated for 871 of the 912 boys attending a secondary school in Stockholm in 1950. When they were divided into 3 groups according to parents' income after tax deduction, no significant difference in weight was found, but the boys from the lowest income group were significantly shorter ($P = 0.05$). At constant age, the correlation between height or weight and income was almost zero. When the grouping was by father's occupation, the sons of "civil servants and other employees" were the tallest and the difference between them and sons of "workers" was highly significant.

The results are compared with those of Key in 1883 and of Broman *et al.* in 1938 (Abst. 2500, Vol. 15). Mean height for the whole age range 10½ to 20½ years has risen by 14.3 cm. since 1883 and mean weight by 11.5 kg., and the figures suggest that this secular change is still continuing. The yearly increase in height is nearly twice that for conscripts from the whole country.—W. M. Deans.

964

BOUILLIÈRE, F., HUARD, P., NGUYEN VAN NHUNG and TRAN Vx. La croissance staturale et segmentaire des Vietnamiens du nord. [Growth in stature and segmentary growth in Vietnamese of the north.] *C.R. Acad. Sci.*, 1954, **238**, 2564-2567.

There is little information on the relative growth ratio of different parts of the human body, and it is impossible, for example, to determine whether climate can affect the relative length of the limbs in some specific nationality. A comparative study has been begun of the growth of different parts of the body of different peoples in their native climates and in others to which they are not suited by heredity, and this paper reports the results of a study on Vietnamese at Hanoi. A table is presented of means by age and sex of stature, leg length, trunk length, and arm length, with standard errors. There is also a graph showing at different statures what proportion of growth in stature is represented by growth in the 3 measures stated above. Stature ranges from 0.85 m. to 1.60 m.

Several conclusions are drawn, among these that growth in leg length is more important in the younger children (aged 3+), and in the later years of growth increase in trunk length becomes more important. This change in relative importance takes place somewhere between 9 and 12 years, before puberty. Growth is completed by 17 years of age, which, the authors state, is earlier than among Europeans.

It is pointed out that a study of Vietnamese born in France would be necessary to determine how far this difference was due to genetic and how far to ecological factors.—A. W. Boyne.

ABE, K. and YANO, K. An analytical study of the growth curve.

YANO, K. A comparative study on the growth in height and weight of normal, blind, and deaf school-children. *Kurume Med. J.*, 1954, **1**, 67-70; 71-84. [Dept. Environmental Hyg., Sch. Med., Kurume Univ., Kurume-shi, Japan.]

Curves of (1) growth in height, (2) rate of increase, (3) rate of relative increase, *i.e.*, (2) ÷ (1), and (4) rate of acceleration for normal, blind, and deaf boys and girls, based on Educational Ministry school statistics for 1950, are reproduced. The rate of increase curve for the handicapped children had several peaks instead of one, *i.e.*, their growth was erratic.

Curves of growth in height and rate of relative increase based on Educational Ministry statistics for 1948-1951 for normal, blind, and deaf boys and girls confirmed the previous findings. Results for weight are stated to be similar. From a further study of the 1951 figures it was concluded that the blind and deaf are inferior to the normal in both height and weight at ages 18 and 19, *i.e.*, when growth is completed, and that their rate of growth is more variable. Individual growth studies extending from 1940 to 1952 on 125 deaf children and 200 normal children from the same localities showed that on the average these deaf children were not retarded in growth, but the group contained more retarded and more advanced in growth than the normal group.

An addendum states that the degree of loss of hearing makes no difference to growth, so that abnormalities are ascribed to the peculiar environment of the deaf.—W. M. Deans.

966

PARNEL, R. W. The physique of Oxford undergraduates. Relationship with weight variation, schooling and habits. *J. Hyg.*, 1954, **52**, 369-378. [Warneford Hosp., Oxford.]

The height and weight of Oxford undergraduates are discussed. It is not stated how they were sampled, but the implication from text and tables is that they are represented by students who attended the pilot student health service from 1947 to 1950. These are compared with the general community divided into social classes and found to be taller and heavier. Comparisons are made between those who came from boarding schools, private day schools and government-aided schools.

Undergraduates were similar in weight and height to those of 1908 to 1910, but the construction of the 2 samples is not compared.

The commoner somatotypes are shown to be taller and heavier than American students of similar somatotypes.

Weight change during university residence is examined, the samples being broken down by origin of students. A sample of female students is similarly analysed. In both sexes the younger students gain more weight. Investigations are made of the association between loss of weight and psychological upset and the association between weight change and the habits of playing games and smoking.—A. W. Boyne.

CLEMENTS, E. M. B. and PICKETT, K. G. **Body-weight of men related to stature, age, and social status. Weight of Scotsmen measured in 1941.**

Chest girth of men related to stature, age, bodyweight, and social status. Chest girth of Scotsmen measured in 1941. *Brit. J. Prev. Social Med.*, 1954, 8, 99-107; 108-116. [Dept. Anat., Univ. Birmingham.]

The extent to which social, geographical, economic and other conditions affect bodyweight of Scotsmen was studied. The men were examined in 1941 by the Scottish medical boards of the Ministry of Labour and National Service.

The mean weight by age-groups presented for each region shows men of the Northern region to be the heaviest and those of the West Central region to be lightest, and also shows a tendency for weight to increase with age. The analysis is subsequently refined, so that log weight is investigated and the effects of stature, age, geography and social class on this transformed variate are considered. Log weight is linearly related to stature; up to age 30 weight increases with age, but beyond that age the trend is small; when age and stature have been taken into account the social classes do not differ significantly.

The sample is random within occupations and age-groups, but is not representative of the civilian population.

By similar methods of analysis, log girth was found to be related to log weight, to stature, and to age. The data were standardised for this relation and it was found that for each social class there were significant differences between the results for different medical boards. It was not possible to say how far this was due to differences in measuring technique and how far to real geographical differences. The standardised girth did not differ significantly between social classes, and was greater in men fit for service than in the unfit. A. W. Boyne.

HRACHOVEC, J. **Sur une formule s'appliquant à la courbe de croissance d'un animal. [A formula for application to the growth curve of an animal.]** *C.R. Acad. Sci.*, 1954, 238, 2356-2358.

It is suggested that the empirical is the most reasonable approach to the problem of obtaining mathematical equations to represent growth and to search for an equation which best approximates to function.

For the rabbit, a third order exponential function represented growth as a function of time. Such an equation also fits the growth of the mouse, horse, cattle, sheep and other domestic animals. The fit of this function to data representing the growth of mice is shown in a graph.

A second order exponential function is not such a good fit for the growth of an animal, but much better for that of a colony of *Vorticella*, whose growth is considered by Teissier to be intermediate between that of a population and an animal. A first order exponential function has already been postulated by others for the growth of a population.—A. W. Boyne.

BHASKAR, S. N., WEINMANN, J. P. and SCHOUR, I. **The growth rate of the tibia of the *ia* rat from 17 days insemination age to 30 days after birth.** *Anat. Rec.*, 1954, 119, 231-245. [Dept. Oral Pathol., Univ. Illinois.]

In rats of strain *ia*, bone tissue is not resorbed and the perichondral splint which first forms around the middle of the cartilaginous tibia persists as a landmark from which the growth rate can be measured. The tibias were studied of 6 rats between 17 days after insemination and birth, 11 rats from birth to 5 days old, 7 between 9 and 12 days and 7 between 15 and 30 days.

Rapid growth occurred at the times of appearance of ossification centres, between 17 and 19 days of foetal age and between 10 and 12 days after birth. The proximal and distal epiphyses grew at about the same rate until 11 days after birth, after which the proximal epiphyses grew the faster. Growth of the tibia was arrested for about 2 days after birth and was then rapid until about the twelfth day, after which it slowed down and secondary centres of ossification appeared. The growth of the medullary cavity and rate of replacement of cartilaginous epiphyses closely corresponded to the rate of growth of the cartilages.

RANKIN, J. J. **Lack of correlation between thymus and body weights during adolescence and early maturity.** *J. Physiol.*, 1954, 125, 316-321. [Univ. Coll. W. Indies, Jamaica.]

In a series of mice [number unstated] killed at ages from birth to 494 days, the maximum weight and length of the thymus was reached at 23 days.

The greatest ratio of thymus weight to body-weight was reached at 14 days, and in early growth there was close correlation between these weights

N.A. and R., January 1955

($r = +0.93$). During adolescence and early maturity the correlation disappeared and there was great fluctuation in thymus weights. Caution is advised in the assessment of experiments on rates of thymic involution.—D. Duncan.

PROBST, V. and ROTH, O. A. Über einen Pflanzen-extrakt mit hormonartiger Wirkung. [A plant extract with hormone-like activity.] *Deutsch. med. Wochenschr.*, 1954, 79, 1271-1274. [Frauenklin., Univ. Tübingen.]

"Alyt", an alcoholic extract obtained from seeds of *Agnus castus* and previously shown to have an effect on the oestrous cycle of rats, was used in experiments on women. The patients studied included 24 with primary or secondary amenorrhoea, 16 with oligo-hypomenorrhoea and 40 with cystic-glandular hyperplasia of the endometrium.

With very few exceptions Alyt produced a distinct rise in the basal temperature, a secretion phase in the histological picture of the endometrium and a progesterone effect in the vaginal smear. The effect of Alyt on the ovaries was shown by ovulation and formation of a corpus luteum. Whether this was a direct or an indirect effect on the ovaries cannot yet be decided. The possible mechanism of the action is discussed.

REPKE, K. and MARKWARDT, F. Versuche zum Lichteinfluss auf die jahreszeitliche Oestrus-periodizität. [Effect of light on the seasonal periodicity of oestrus.] *Arch. exp. Pathol. Pharmacol.*, 1954, 223, 259-270. [Pharmakol. Inst., Univ. Greifswald.]

The hypothesis that the role of light in the seasonal occurrence of oestrus might consist in conversion in the skin of the relatively inert oestrone to the relatively active oestradiol 17 β was tested in rats, which were irradiated after receiving injections of oestrone. There was no increase of activity. The effect of light is therefore thought to be of nervous origin, transmitted via the retina and hypothalamus to the pituitary to cause liberation of gonadotropic hormones.—I. Leitch.

973

CLEMETSON, C. A. B. The placental transfer of amino-acids in normal and toxæmic pregnancy. *J. Obstet. Gynaecol. Brit. Empire*, 1954, 61, 364-371. [University Coll. Hosp., London.]

Plasma α -amino-acid N levels of maternal and foetal blood were estimated in 43 cases immediately after delivery of the baby. In 18, pregnancy

was apparently normal, but in 7 of these the umbilical cord was found coiled around the baby's neck. There were 9 women with mild toxæmia, 10 with pre-eclampsia and 4 with toxæmia and with the cord round the baby's neck.

The mean foetal amino-acid N levels were similar in all groups, slightly below 5 mg. per 100 ml. The mean maternal amino-acid N level was 2.96 ± 0.11 mg. per 100 ml. in the normal group, 3.23 ± 0.21 in mild toxæmia and 3.52 ± 0.22 in pre-eclampsia. When the cord was round the baby's neck the mean maternal level was 3.52 ± 0.15 and 3.65 ± 0.22 mg. per 100 ml. in the non-toxæmic and toxæmic groups, respectively.

It is concluded that amino-acids are actively transferred from the maternal to the foetal circulation across the placenta and that their level rises in the maternal blood when this transfer is impeded by an obstructed umbilical cord or when placental function is impaired in toxæmia of pregnancy.

RÖTTGER, H. Über den Wasserhaushalt in der physiologischen und toxischen Schwangerschaft. 2. Der Wasserhaushalt bei Schwangerschaftsspättoxikosen. [Water metabolism in normal and toxæmic pregnancy. 2. Water metabolism in toxæmia of late pregnancy.] *Arch. Gynäkol.*, 1953-54, 184, 629-642. [Frauenklin., Med. Akad. Düsseldorf.]

For part 1 see Abst. 3480, Vol. 24. The water metabolism was studied by the methods there described in 18 patients with renal disorders of pregnancy, pre-eclampsia or eclampsia, all with manifest oedema.

In 15 of the 18 cases plasma volume was below the mean found in normal pregnancy at the corresponding stage, but interstitial tissue fluid was much increased, often by 8 to 10 litres above that of the normal non-pregnant woman. The changes were rapidly reversed in the puerperium; the plasma volume increased despite loss of blood at parturition, and the oedema was reduced by diuresis.

KAYSER, H. W. Die Permeabilität der Placenta für P_{22} , zugleich ein Beitrag zur Frage der Blutdurchströmung des intervillösen Raumes. [Permeability of the placenta to ^{32}P ; a contribution to the problem of the blood circulation

in the intervillous space.] *Arch. Gynäkol.*, 1953-54, 184, 385-413. [Frauenklin., Univ. Kiel.]

Data are presented from experiments in which 30 to 40 $\mu\text{C.}^{52}\text{P}$ in 5 ml. saline was injected into the right cubital vein of 50 women in labour. Immediately after delivery blood was taken from the left cubital vein and from the cord. Recorded are age, parity, earlier abortions, menstrual age of the foetus, blood pressure, duration of labour; weight and length of the child and weight of the placenta; haematocrit, Hb and red cell count for both mother and child; interval between injection and delivery and the activity of whole blood, plasma, and erythrocytes in both maternal and cord blood, and activity of the placenta.

The activity per unit volume of cord plasma equalled that of maternal plasma after about 1 hr. and thereafter equalled it or exceeded it by up to 100 per cent. In red corpuscles cord activity on the average rose to about 40 per cent. of maternal at 1 hr., but did not on the average rise above that level. Total activity in maternal blood always exceeded that in foetal. It is computed that a total of about 0.17 $\mu\text{C.}$ was transferred to the foetus.

The activity of the several layers of the placenta was the same 2 min. after injection and remained constant for a long time. From this it is computed that the rate of blood flow to supply the placenta is not slow, as has been supposed, but that the maternal blood in the intervillous spaces is renewed at about the same rate as foetal blood in the placental vessels, with complete renewal in about 1 min.—I. Leitch.

977

ROMBAUTS, P., BOURDEL, G. and JACQUOT, R. Sur la signification de l'étendue des facultés anabolisantes des femelles gestantes. [Significance of the increased anabolism of pregnant female animals.] *C.R. Acad. Sci.*, 1954, 238, 2260-2262.

During a preliminary period, 24 adult female rats were given a diet containing 20 per cent. protein as casein, supplemented by cystine; although their weights remained at about 200 g. after the eighth day, they were in positive N balance at a level of about +15 per cent. After 74 days, the rats were divided into 5 groups: (1) pregnant animals, given a 20 per cent. protein diet to appetite; (2) and (3), respectively, pregnant and non-pregnant animals given a diet containing N at a maintenance level, 100 mg. daily, plus an allowance calculated to provide twice the N demands of the products of conception; (4) and (5), respectively, pregnant and non-pregnant animals receiving 100 mg. N daily.

The rats in groups 2 and 3 ate about the same

amounts, 5.7 g. dry matter daily; those in group 4 about 9.2 g. dry matter. The weight of control animals in groups 3 and 5 remained stationary, all pregnant animals gained weight; their weights post partum were 40 per cent. (group 1), 25 per cent. (group 2) and 19 per cent. (group 4) above starting weights. In groups 2, 3 and 4, change to the experimental diets resulted in a negative N balance for 4 days, but the balance then became and remained positive, even in group 4 where N intake was at maintenance level for the non-pregnant animal. In group 5 the N balance was in equilibrium.—A. M. Thomson.

978

FERGUSON, N. L. Changes in the liver fat of the pregnant sheep at different levels of nutrition and during starvation. *Brit. J. Nutrition*, 1954, 8, 269-280. [Sch. Agric., King's Coll., Univ. Durham.]

From mating to the one-hundredth day of pregnancy, 44 halfbred ewes, fed individually indoors, increased in weight from 149 to 168 lb. Fifteen ewes were then fed on a high-plane diet and gained a further 17 lb. in the 138th day of pregnancy. Eighteen ewes were placed on a low-plane diet and lost 32 lb. in the same period.

The well-fed pregnant ewes had 13.1 per cent. liver fat, no more than non-pregnant ewes, but the amount rose considerably with growth. Starved pregnant ewes were starved. Liver fat of ewes on the low-plane diet from the one-hundredth day of pregnancy rose to 26.7 per cent. by the 138th day, but starvation imposed at this time reduced the fat content. Pregnancy reduced the fat content of 13 low-plane ewes before starvation was imposed.

979

FERGUSON, N. L. Relationship between maternal liver fat and foetal weight in ovine pregnancy. *Nature*, 1954, 174, 277-278. [Sch. Agric., King's Coll., Univ. Durham.]

Eight ewes fed on a high plane throughout pregnancy were compared with 6 fed on this high plane for the first 100 days of pregnancy and thereafter on a low plane, on which they lost much weight. Total liver fat of low-plane ewes (6 twins) was 8.8 and of high-plane ewes (4 twins, 4 singles) 26.7 per cent. of fresh weight. Significant positive correlation was found between maternal liver fat and weight of foetuses in the low-plane but not in the high-plane ewes. In the latter the body reserves did not appear to have been used.

KARVONEN, M. J. and RÄIHÄ, N. Permeability of placenta of the guinea pig to glucose and fructose. *Acta physiol. scand.*, 1954, 31, 194-202. [Inst. Occupational Health, Helsinki.]

N.A. and R., January 1955

The permeability of the placenta of the guinea-pig to glucose and fructose was studied *in situ* by infusing the sugar into the maternal circulation, or by injecting it into the foetus. When glucose was infused into the mother, the rise in foetal blood sugar was closely parallel to the rise of glucose in the mother, showing that the placenta was freely permeable to glucose coming from the maternal side. When glucose was injected into the foetus, the glucose level fell fairly rapidly to that of the mother, indicating that the placenta was permeable to glucose from the foetal side. The transfer of glucose from the foetus was possibly somewhat slower than from mother to foetus, but further study is needed on the point. The transfer of fructose through the placenta in each direction was considerably slower than that of glucose. It is concluded that the transfer of glucose through placenta in both directions is an active process in the guinea-pig, as it is in the sheep, in spite of the differences in carbohydrate metabolism between the 2 species.—M. B. Richards.

HYTTEN, F. E. Clinical and chemical studies in human lactation. 7. The effect of differences in yield and composition of milk on the infant's weight gain and the duration of breast-feeding. *Brit. Med. J.*, 1954, i, 1410-1413. [*Midwifery Dept., Univ. Aberdeen.*]

A study of the weight gain of infants and duration of breast feeding in women whose milk was analysed on the seventh day showed that only yield and fat content were related to the clinical findings. Seventh-day milk fat output was directly related to the weight gain of the infants in hospital from the third to the seventh day. In a 13-week follow-up study of 148 of the 167 women whose milk was sampled, fat output on the seventh day was directly related to the duration of breast feeding. Accurate weights of 83 infants available during the follow-up study showed a direct relation between seventh-day fat output and weight gain during the first month.—F. C. Aitken.

984

BATEMAN, N. The measurement of milk production of mice through preweaning growth of suckling young. *Physiol. Zool.*, 1954, 27, 163-173. [*Inst. Animal Genetics, Edinburgh.*]

Vol. 25, No. 1

The relative contribution of the mother and the young to variations in growth was investigated during a study of milk production in the mouse. The weight at 12 days of age of whole litters and of individual young was recorded and calculations were made of variance due to differences between and within families. Prenatal and postnatal maternal effects on growth were examined and also the effect of the number in the litter. The 12-day weight of the whole litter is not a reliable guide to lactation performance unless there is independent evidence that postnatal or lactational factors are the sole variants in the study.

FOURNIER, P., DUPUIS, Y., SUSBIELLE, H. and BOURDEAU, A. L'action protectrice du lactose sur le squelette de la ratte allaitante. [Protective action of lactose on the skeleton of the lactating rat.] *C.R. Soc. Biol.*, 1954, 148, 265-268. [*Lab. Physiol. Nutrit., École Hautes-Études, Paris.*]

The experiment has been described in *Abst. 3492, Vol. 24.*

The prevention of loss of skeletal Ca in the lactating rats receiving 12 per cent. lactose was due to greatly increased absorption and utilisation of dietary Ca, the Ca output being the same as in rats on standard diet.—D. Duncan.

ROMJN, C. Untersuchungen über künstliche Bebrütung von Hühnereiern. 1. Physiologische Untersuchungen. [Artificial incubation of hen eggs. 1. Physiological investigations.] *Arch. Geflügelk.*, 1954, 18, 173-183. [*Lab. Vet.-Physiol., Reichsuniv., Utrecht.*] English summary.

This resumé of work by the author on the chick embryo, reported more fully elsewhere, includes a table showing the bodyweight, oxygen consumption and R.Q. corrected for CO₂ given off by the shell for each day of incubation, as well as a diagram showing the changes in composition of the gas in the air space. Oxygen consumption begins to rise rapidly about the 10th day, along with bodyweight, and the percentage of oxygen in the air space falls. Diffusion experiments showed that most of the oxygen required has to come through the part of the egg shell covering the air space. The most favourable conditions were a relative humidity of from 56 to 58 per cent., raised to 75 or even more when the chicks began to emerge.

987

COTTE, J. La choline de l'oeuf en incubation. [Choline in the egg during incubation.] *C.R. Acad. Sci.*, 1954, 238, 2569-2571.

The total choline content of the hen's egg remained constant up to the 13th day, then decreased steeply during the 3rd week of incubation. The choline in the embryo increased throughout incubation, more rapidly than embryo weight up to the 15th day and then more slowly. The daily choline increment per 100 g. embryo reached a maximum, as did also the free choline in the remainder of the egg, at the 14th day. Both then fell as the total choline content decreased.

It was concluded that the choline as lecithin was converted to a water-soluble form before being metabolised by the embryo.—A. Hepburn.

TYLER, C. Studies on egg shells. 4. The site of deposition of radioactive calcium and phosphorus. *J. Sci. Food Agric.*, 1954, 5, 335-339. [Dept. Agric. Chem., Univ. Reading.]

Two laying pullets were fed on a diet of normal composition with part of the Ca in radio-active form. The total Ca required for egg production was included in the mash and the whole daily allowance of mash was consumed between 9.30 and 11.00 a.m. each day. For 7 days the time was noted at which each egg was laid. Collection of eggs was continued for a further 7 days after radio-active Ca was discontinued.

Antoradiographs of shell sections were prepared from each egg laid and by comparing the patterns of radio-activity of eggs laid at different times it was possible to suggest which part of each shell was formed from dietary and which from bone Ca.

Most eggs were laid during the morning, and with only one feed daily, the shells of these eggs were formed in the early stages from food Ca and later from bone Ca. Shells of eggs laid after about 3.30 p.m. contained food Ca in the outer parts, showing that by this time food Ca consumed between 9.30 and 11.00 a.m. was available in the shell gland.

The experiment was repeated with radio-active P. Most of the small amount of P associated with the shells was on or near the surface.

BOGDONOFF, M. D., SHOCK, N. W. and PARSONS, J. The effects of stilbestrol on the retention of nitrogen, calcium, phosphorus, and potassium in aged males with and without osteoporosis. *J. Gerontol.*, 1954, 9, 262-275. [Sect. Gerontol., Nat. Heart Inst., Nat. Insts. Health, Bethesda, Md.]

Six aged males, 3 with and 3 without evidence of osteoporosis, were studied. Four control 5-day periods were each followed by 4 similar periods when 2 mg. stilbestrol was administered by mouth 3 times daily; each experimental period was followed by a 5-day recovery period. Food intake was constant through all 12 periods; the energy intake was 2600 Cal. daily and, from chemical analysis of the diets, the daily intake was found to be: N 16.8 g., P 1322 mg., K 70 m. equiv. and Ca 624 mg. Fasting blood samples were taken at the end of periods 1, 3, 5, 6, 8, 9, 11 and 12 for estimation of Ca, P, total protein, albumin, globulin, K and alkaline phosphatase. Urine and faeces were also analysed.

Stilbestrol had no significant effect on the retention of N in the 6 subjects on diets permitting positive N balance. The retention of K was similar to that of N during the control periods, but administration of stilbestrol reduced K retention. Stilbestrol reduced urinary excretion of Ca in all 6 subjects, but there was a significant net retention in only 2 subjects, both of whom had osteoporosis. P retention was not affected by stilbestrol in the normal subjects, but was increased in the 2 subjects who showed increased Ca retentions.—G. F. Garton.

CHESROW, E. J. and BLEYER, J. M. The glucose tolerance test on the aged. *Geriatrics*, 1954, 9, 276-282. [Cook County Inst., Oak Forest, Ill.]

The subjects were 46 men and 34 women aged from 60 to 109 years, 41 going about and 39 confined to bed or chair. Oral glucose tolerance tests were made on all, and intravenous tests 8 days later on those whose oral test curves were abnormally prolonged.

In 9 inactive and 9 active patients the blood sugar curves in the oral test were prolonged beyond the third hour, resembling the curves of diabetes mellitus. There was no uniform relation of tolerance curve and age within the range tested. Intravenous tests were made on 16 of these 18 patients, and all gave normal non-diabetic curves. It is suggested that the oral tolerance test should be prolonged to at least 3 hr. in people over 60, and that intravenous tests are valuable in differentiating "normal" prolonged curves from those of diabetes mellitus.—D. Duncan.

EXPERIMENTAL STUDIES OF IMMUNITY AND MICRO-ORGANISMS

995

- SINGH, J., NAIR, C. P., RAMAKRISHNAN, S. P. and RAY, A. P. Studies on Nuri strain of *P. knowlesi*. 1. Effect of milk diet on blood-induced infection. *Indian J. Malariol.*, 1953, 7, 253-260. [Malaria Inst. India, Delhi.]

Of 14 adult rhesus monkeys, 3 received a normal diet of gram, wheat flour, vegetables and fruit, 2 were starved after inoculation and for 1 or 3 days before it, and 7 were given 1½ oz. full-cream milk powder made up with water, 3 times a day by stomach tube. Two were used for inoculation from some of the others. All the monkeys except the last 2 were inoculated intravenously with, per kg. bodyweight, 5 million red blood cells parasitised with the Nuri strain of *Plasmodium knowlesi*. Blood counts for parasites were made twice daily.

With normal diet or starvation the infection ran a quickly fatal course. Milk diet exercised a powerful protective effect, which varied in degree according to the time the diet was begun in relation to the time of inoculation. If milk diet was begun some days before inoculation, the infection did not become patent as long as the milk was continued, but monkeys inoculated with blood from those thus treated eventually developed malaria. Milk diet given in addition to standard diet had much the same effect as milk diet alone.

Effect of glucose, biotin, para-aminobenzoic acid and methionine on the course of blood-induced infection in starving albino rats. *Indian J. Malariol.*, 1953, 7, 225-228. [Malaria Inst. India, Delhi.]

Thirty rats, 6 months old, were inoculated with one million organisms of *P. berghei*. They were then starved for 10 days with water to appetite. Small groups were given daily 0.75 mg. p-aminobenzoic acid or 0.05 mg. biotin intraperitoneally, or 72 mg. methionine subcutaneously, or 12 g.

glucose orally, or water or saline intraperitoneally; one group received a standard complete diet. Blood counts were made daily for parasites.

With starvation, and glucose or biotin or injections of water or saline there was little growth of parasites. With p-aminobenzoic acid there was a small increase, and with methionine increase was considerable, though not as great as with standard diet, suggesting that methionine was an essential nutrient for the parasite.—E. M. Hume.

- DREIZEN, S., MOSNY, J. J., GILLEY, E. J. and SPIES, T. D. The amino acid requirements of oral acidogenic microorganisms associated with human dental caries. *J. Dent. Res.*, 1954, 33, 339-345. [Dept. Nutrit., Northwestern Univ. Med. Sch., Chicago, Ill.]

Pure cultures of oral strains of *Lactobacillus acidophilus*, *Streptococcus salivarius*, *Staphylococcus albus* and a glucose-fermenting *Saccharomyces* were isolated from patients with active dental caries. The requirements of each for the biologically active amino-acids found in human saliva were estimated.

None of the 19 acids tested was required by *Streptococcus salivarius* or the *Saccharomyces*, but 3 were needed for *Staphylococcus albus* and 6 for *Lactobacillus acidophilus*. With mixtures of the 4 micro-organisms acid production was significantly less in tubes lacking the amino-acids required by the lactobacillus. In pure cultures of *Lactobacillus acidophilus* and *Staphylococcus albus*, the amino-acid requirements varied with strain as well as with species. All 6 classes of amino-acids were required by the lactobacillus. The streptococcus required the monoaminodicarboxylic acids and

the sulphur-containing amino-acids, and *Staphylococcus albus* required the heterocyclic amino-acids, but neither required the diaminomono-carboxylic acids. In all the other acids tested these 2 strains grew poorly. In contrast, the growth of the mixed cultures was significantly reduced when any one class of acids was absent.

In mixed cultures of acid-forming bacteria prepared from saliva of 15 patients with dental caries, the distribution of types of bacteria was lactobacilli 11 cultures, streptococci 15, staphylococci 6, "yeast" 5, diphtheroids 2, *Neisseria* 2 and diplococci 2. Growth of these mixed cultures was poorest when glutamic acid was absent, and sub-maximum growth was obtained when tyrosine, tryptophan, arginine, isoleucine, leucine, valine, cystine, methionine, or phenylalanine was absent. In cultures containing lactobacilli, the greatest inhibition was found when the amino-acids required by the pure culture of lactobacillus were absent. Acid production in mixed cultures was least when monoaminodicarboxylic acids or sulphur-containing acids were withheld.

HARTLES, R. L., SLACK, G. L. and WASDELL, M. R. The metabolism of the oral flora. 3. The utilisation of different carbohydrates by a strain of lactobacillus isolated from the mouth. *Brit. Dent. J.*, 1954, 97, 67-69. [Dept. Biochem., Sch. Dent. Surg., Univ. Liverpool.]

A strain of lactobacillus isolated from a 5½-year-old child with no clinically detectable caries had a limited ability to ferment carbohydrates; after 24 hours' incubation only glucose, cellobiose and salicin were fermented, and after 96 hr. maltose and lactose were sometimes fermented, but sucrose and raffinose were not.

In washed suspensions of the culture the only marked glucosidase was a β -glucosidase. Cellobiose, gentiobiose and salicin were all metabolised. Some trehalose activity was found. Maltose, turanose, maltotriose, melezitose, sucrose, raffinose, lactose and melibiose were not broken down. Glucose, fructose and mannose were readily broken down and to a less extent galactose. Ribose was slightly metabolised, but xylose and arabinose, dulcitol, mannitol, gluconic acid and rhamnose were not.

The synthesis of invertose or maltose was not stimulated by subculturing in the presence of the appropriate sugar.

The pH of the saliva from which the lactobacillus was isolated was 7.0 on 3 days separated by 3-day intervals. The lactobacillus counts per ml. saliva on these 3 days were 3600, 48,230 and 21,600, and Snyder's test for caries susceptibility gave values of 2, 3 and 3, where 0 = no activity and 4 = high caries activity.—M. J. Dobson.

SHOCKMAN, G. D. and TOENNIES, G. Growth response of *Streptococcus faecalis* to the stereoisomers of methionine and some derivatives. *Arch. Biochem. Biophys.*, 1954, 50, 1-8. [Lankenau Hosp. Res. Inst., Philadelphia, Pa.]

Streptococcus faecalis utilised D-methionine during its post-logarithmic growth phase if L-methionine was present, and independently of pyridoxal or pyridoxamine. The isomers of L-methionine sulphoxide gave growth curves similar to that of L-methionine. The 2 isomers of DL-methionine sulphoxide at first gave a response proportional to their L-methionine sulphoxide contents, but later utilisation of D-methionine compounds became apparent. The N-formyl and N-acetyl derivatives of methionine gave responses similar to those of their parent compounds. Neither DL-methionine sulphone nor L-methionine methyl sulphonium ion produced any growth response. The ketone body corresponding to methionine partly replaced methionine when pyridoxamine was also present.

SHOCKMAN, G. D. and TOENNIES, G. Formation of D-methionine from L- by *Streptococcus faecalis*. *Arch. Biochem. Biophys.*, 1954, 50, 9-17. [Lankenau Hosp. Res. Inst., Philadelphia, Pa.]

When *Streptococcus faecalis* was grown with L-methionine only 67 per cent. of the latter could be recovered from the cell hydrolysate and the medium. With ^{35}S L-methionine nearly 20 per cent. of the ^{35}S remained unassimilated in a form which ran on chromatograms like methionine or its sulphoxide. D-Methionine was identified by isotope dilution in quantities accounting for part of the loss. Further loss could be accounted for as methionine sulphoxide which was formed by incubation of methionine in the medium alone. This reaction was catalysed by the riboflavin present.—A. Dobson.

MANN, S. O. and OXFORD, A. E. Studies of some presumptive lactobacilli isolated from the rumens of young calves. *J. Gen. Microbiol.*, 1954, 11, 83-90. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]

In the course of a study of the effects of aureomycin, 13 Gram-positive rods were isolated from

N.A. and R., January 1955

the rumen of calves. Of these 10 were catalase-negative, and were studied with methods for lactobacilli. The other 3 were catalase-positive and were not studied further. The 10 isolates fell into 3 groups, the morphology and biochemical reactions of which are described.

The authors do not claim to have isolated all the lactobacilli from the rumens of the calves, but it is considered important that lactobacilli were specially plentiful in the youngest calves and that no catalase-negative rods were isolated from the oldest group of calves, killed some weeks after milk feeding ceased. It is suggested that lactobacilli are organisms of passage capable of multiplication in the rumen of young calves.

MANN, S. O., MASSON, F. M. and OXFORD, A. E. **Effect of feeding aureomycin to calves upon the establishment of their normal rumen microflora and microfauna.** *Brit. J. Nutrition*, 1954, 8, 246-252. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]

The 3 groups of 3 calves each were reared to 5, 8 and 12½ weeks of age, respectively, and then slaughtered. Milk and calf gruel were given to 6 weeks of age, and gruel but no milk thereafter. From the third week onwards, linseed meal, hay and oats were offered. Grass was given to appetite after the sixth week. Pure aureomycin hydrochloride was given to 2 calves in each group at a daily rate of 40 mg. to 6 weeks of age. Treated calves remaining on experiment after this age received 60 mg. daily. The third calf in each group was used as a control and received no aureomycin. After slaughter the contents of the rumen and reticulum, omasum and abomasum were weighed and were subjected to protozoological and bacteriological examination. The concentration of aureomycin in the rumen, omasum and abomasum was estimated by the pad plate method.

The growth rate of the treated calves was slightly higher than that of the controls. The rumen contents of the aureomycin-fed calves were heavier and less acid than those of the controls, and more quickly reached a pH suitable for large-scale bacterial action.

A detectable concentration of aureomycin was found in the abomasum and traces in the omasum. None was found in the rumen or caecum. It was concluded that the aureomycin had no direct effect on the rumen micro-organisms.—J. N. Aitken.

1005

FAUCONNEAU, G., FRANÇOIS, A. C., LEROY, A. M. and ZELTER, S. Z. **Processus digestifs des ruminants. 1. Étude in-vitro de la digestion du foin de luzerne. [Digestion processes in the ruminant. 1. Study in vitro of the digestibility**

Vol. 25, No. 1

of alfalfa hay.] *Ann. Zootech.*, 1953, 2, No. 4, 275-284. [Lab. Recherches Zootech., Inst. Nat. Agronom., Paris.]

Rumen fluid from newly-killed sheep was incubated in artificial saliva medium with alfalfa hay as substrate, and the gases were collected.

The mean proportions of volatile fatty acids of the rumen fluid before incubation were acetic 65.7, propionic 19.9 and butyric 14.4 per cent., and after 48 hr. of incubation 60.6, 28.0 and 11.5. On the average 66 per cent. of the reducing sugars and 42.7 per cent. of the cellulose in the hay were utilised. The values for carbohydrate digestion and total volatile fatty acid formation were almost identical with those obtained *in vivo*, although the proportions of the fatty acids differed. About 83.8 per cent. of the carbohydrate lost could be accounted for as volatile fatty acid. The production of volatile fatty acids was about 224 (range 153.4 to 263.4) g. per kg. alfalfa hay dry matter.

D. Duncan.

1006

BENTLEY, O. G., JOHNSON, R. R., VANECKO, S. and HUNT, C. H. **Studies on factors needed by rumen microorganisms for cellulose digestion in vitro.** *J. Animal Sci.*, 1954, 13, 581-593. [Ohio Agric. Exp. Stat., Wooster.]

Samples taken through a fistula from the rumen of a steer fed on alfalfa were incubated with a basal medium and cellulose for 24 to 48 hr. The amount of cellulose digested was taken as a measure of microbiological activity.

Cellulose digestion in the basal medium was slow. The addition of autoclaved rumen juice increased cellulose digestion as much as did whole rumen juice. Increases in activity were obtained when water extracts of several plant materials or roughages were added. Alfalfa leaf meal, molasses, yeast and rumen juice were most effective. Of the B vitamins tested, biotin, *p*-aminobenzoic acid and vitamin B₁₂ were beneficial. A mixture of alfalfa ash, purines and uracil was ineffective, but combinations of either alfalfa ash or purines and uracil along with the 3 B vitamins already found effective were better than the B vitamins alone.

A substance which increased cellulose digestion was partly isolated from rumen juice.

M. J. Dobson.

1007

KITTS, W. D. and UNDERKOFER, L. A. **Hydrolytic products of cellulose and the cellulolytic enzymes.** *J. Agric. Food Chem.*, 1954, 2, 639-645. [Chem. Dept., Iowa State Coll., Ames.]
Samples of rumen contents from a fistula were strained and inoculated into a synthetic medium containing 1 per cent. cellulose and gassed with CO₂.

Carboxymethylcellulose (CMC) was digested rapidly, finely ground filter paper and alphasel slowly. Thymol, chloroform, sodium fluoride, toluene, *m*-xylene and iodoacetic acid were, in this order, decreasingly effective as inhibitors of the conversion of sugars to volatile fatty acids. In most of the subsequent experiments thymol or NaF was used to stop the fermentation of cellulose at the glucose stage. With ground filter paper and CMC as substrates in fermentation tests at 40° C., only glucose was detected after 48 hr., and no cellobiose. When 2 per cent. cellulose was used, after 2 hr. the principal intermediate was glucose. Slight traces of cellobiose were found up to 6 hr., but thereafter none. Faint spots of xylose were seen on the chromatograms from each hourly sample for 16 hr. No oligosaccharide greater than cellobiose was ever found.

A cell-free extract of rumen micro-organisms possessed good cellulolytic activity. No short-chain volatile fatty acids were formed in 24 hours' incubation. For the first few hours glucose only was detected. After 20 and 24 hr. traces of xylose were found, suggesting that the extract contained an enzyme hydrolysing xylans to xylose. Cellobiose was not detected. Further experiments showed that cellobiose was hydrolysed to glucose very quickly, and this explained the difficulty in detecting cellobiose when cellulose was fermented.

A cell-free extract from a pure culture of a rumen organism hydrolysed cellulose to glucose. No other product was detected on chromatograms.

1008

McNAUGHT, M. L., SMITH, J. A. B. and BLACK, W. A. P. The utilization of carbohydrates of seaweed by rumen microflora *in vitro*. *J. Sci. Food Agric.*, 1954, 5, 350-352. [Hannah Dairy Res. Inst., Kirkhill, Ayr.]

Rumen micro-organisms *in vitro* were able to utilise laminarin, but it did not produce as much protein synthesis as maltose. Fucoidin and L-fucose were not utilised. The fronds, but not the stipes, of *Laminaria cloustoni*, one of the commonest seaweeds on British coasts, supported bacterial activity to about the same extent as maltose. No inhibitory substance was found in the stipes. *Ascophyllum nodosum* supported little activity and when it was incubated with maltose it reduced the value of the maltose. Up to 36 per cent. laminarin may be found, on a dry matter basis, in *L. cloustoni*. It is the only constituent of seaweed so far investigated by the authors that is readily utilised by rumen bacteria.—M. J. Dobson.

1009

BELASCO, I. J. New nitrogen feed compounds for ruminants. A laboratory evaluation. *J. Animal Sci.*, 1954, 13, 601-610. [Polychem. Dept.,

E. I. du Pont de Nemours and Co., Inc., Wilmington, Del.]

Numerous nitrogenous compounds were examined by an artificial rumen technique similar to that described by Burroughs *et al.* (Abst. 490, Vol. 20). Subcultures were made at the end of 24 hr. and repeated for 4 successive 24-hr. periods. Each series of fermentations had 2 controls, a positive, with urea at a level of N equivalent to that in the experimental flasks, and a negative, with no additional N other than that in the inoculum on the first day. Analyses were made for NH₃ and cellulose and the results were compared by expressing them as a percentage of the response obtained with urea.

The compounds tested belonged to the following groups and numbered 16 urea derivatives, 14 amides, 10 amidines, 16 ammonium salts, both organic and inorganic, and 19 other organic substances in a miscellaneous group.

Among ammonium salts, succinate, lactate, formate, α -ketoglutarate and malate showed rates of N utilisation higher, and free NH₃ levels lower, than those with urea or the other NH₄ salts; with them bacterial growth was excellent. The guanidine salts, carbonate, hydrochloride and acetate, also were valuable; creatinine and creatine slightly less. Amides of monocarboxylic acids provided available N, but with them the rate of cellulose digestion was less than with urea. The diamides of dicarboxylic acids were poor sources of N. Among purine derivatives uric acid and allantoin could be utilised by rumen microflora.

D. Harvey.

ANDERSEN, H. E. Changes of the intestinal flora produced by peroral administration of penicillin in normal swine. *Nord. Vet.-Med.*, 1954, 6, 622-642. [Royal Vet. Agric. Coll., Copenhagen.] German and Danish summaries.

Doses of 60,000 I.U. procaine penicillin were given by mouth to one or two pigs for 4, 8, 12 and 21 days, respectively. In another experiment half of a litter of newly-weaned pigs received 15,000 I.U. per head daily for 135 days.

With the large dose streptococci disappeared almost completely in the first week. Non-haemolytic staphylococci were apparently unaffected. Lactobacilli were reduced; coliform bacteria greatly increased in number and were found as far up the gut as the stomach, compared with the lower jejunum in control pigs. After 21 days the distribution of lactobacilli and coliform bacteria in the 2 penicillin-fed pigs was not consistent. With the lower dose the differences in the distribution of coliform bacteria and lactobacilli were also less conspicuous. Coliform bacteria were not detected in the anterior regions of the gut.

It is suggested that during prolonged treatment with penicillin the intestinal micro-organisms had become partly adapted.—M. J. Dobson.

1011

RHODES, R. A., SARLES, W. B., MONSON, W. J., HARPER, A. E. and ELVEHJEM, C. A. Stimulation and inhibition by antibiotics of intestinal bacteria in chicks. *J. Nutrition*, 1954, 53, 289-302. [Dept. Bacteriol., Univ. Wisconsin, Madison.]

Chicks on diets with 25 µg. per 100 g. or no folic acid and receiving antibiotics grew better than those not receiving antibiotics. The number of coliform bacteria in the intestine of chicks receiving antibiotics generally increased and the number of

lactobacilli generally decreased. Bacitracin with penicillin increased the number of coliform bacteria, most in the lower intestine, and almost eliminated lactobacilli. Aureomycin was less effective in the elimination of lactobacilli, but appeared to increase the number of coliform bacteria, especially in the upper intestine. Bacitracin tended to accumulate in the caeca.

It is concluded that not only may the antibiotics cause increases in coliform organisms and therefore increases in the amount of folic acid formed in the gut, but by reduction of the numbers of lactobacilli may also make more of the folic acid available to the host.—M. J. Dobson.

MISCELLANEOUS FEEDING EXPERIMENTS

1012

WALDSTEIN, S. S., SCHOOLMAN, H. M. and POPPER, H. The effect of feeding large amounts of emulsifiers polyoxyethylene (20) sorbitan monostearate (Tween 60) and sorbitan monostearate (Span 60) to humans. *Amer. J. Digest. Dis.*, 1954, 21, 181-185. [Hektoen Inst. Med. Res., Cook County Hosp., Chicago, Ill.]

Tween 60 was given to 19 hospital patients without metabolic disorder, Span 60 to 16, 6 g. daily in 2 doses for 28 days, and a placebo to 9, all in similar gelatine capsules. Members of the hospital staff, 3 groups of 10, also participated. Laboratory tests made beforehand and after 14 and 28 days included studies of blood and urine and liver function tests.

There was no clinically recognisable adverse effect and no change in urine, blood picture, or blood proteins, cholesterol, phospholipins, N.P.N. or urea N was found. Doubt about the variable results of bromosulphalein retention tests was dispelled by a re-test with another batch of patients. It was concluded that there was no evidence of any deleterious effect in man of these emulsifying agents in doses much larger than would be ingested normally in foods or pharmaceutical preparations.

SUR, G., KUMARI REDDY, S., SWAMINATHAN, M. and SUBRAHMANYAN, V. Supplementary value of food yeast (*Torula utilis*) to poor vegetarian diets based on cereals. *Bull. Central Food Technol. Res. Inst. Mysore*, 1954, 3, 111-112.

The possibility of using food yeast as a supplement to human diets was further investigated in growth experiments with rats. Replacement of part of the *ragi* or milo of the diet by 5 per cent. food yeast greatly stimulated growth; the effect was less with *jowar*, rice or whole wheat.—J. S. Thomson.

BELL, J. M. and GIDYK, M. The effects of frost damage on the nutritional value of wheat. *Canad. J. Agric. Sci.*, 1954, 34, 305-312. [Dept. Animal Husb., Univ. Saskatchewan, Saskatoon.]

Analyses were made of 4 samples of wheat which had been frosted at different stages of maturity and weighed 57, 52, 44 and 28 lb. per bushel, the last 2 being well below milling quality. A sample of elite seed weighing 63 lb. per bushel was used as control.

Wheat weighing as little as 44 lb. per bushel closely resembled sound wheat in composition. In the poorest sample there were slight increases in percentage of protein, crude fibre, ash and ether extract and a corresponding decrease in N-free extract.

Growth experiments with mice in which starch, protein as skimmed milk powder or linseed meal and B vitamins as brewer's yeast were added to the different grades of wheat showed that the nutritive value of wheat weighing as little as 44 lb. per bushel was not seriously affected by freezing; the vitamin B content was adequate. The addition of the supplements, with minerals and fat-soluble vitamins, to wheat weighing 28 lb. per bushel did not effect full restoration of nutritive value, indicating changes not explained by changes in chemical composition.

Antibiotics containing vitamin B₁₂ slightly improved the feeding value of wheat weighing 63 or 44 lb. per bushel, but depressed growth on wheat weighing 28 lb. Addition of methionine to all rations depressed growth, suggesting a toxic effect.

It is suggested that bulkiness is responsible for the decreased feeding value of badly frosted wheat.

J. S. Thomson.

1015

MORIMOTO, H. and YOSHIDA, M. **On the nutritive value of starches. 1.** *Bull. Nat. Inst. Agric. Sci., Japan* [G], 1954, 8, 43-51. Japanese summary.

The digestibility of N-free extracts of maize, wheat, sweet potato and potato starches was compared in trials with cocks; in that order coefficients were 100, 99, 90 and 40 per cent.

In feeding experiments with rats given these starches to appetite or in restricted amount, growth was poorest with potato starch, and dilatation of the caecum was common. Sweet potato starch was slightly inferior to the cereal starches for growth and, like them, did not cause dilatation of the caecum. When potato starch was given to appetite after having been boiled for 15 min. the caecum was not enlarged, but growth remained poorer than with the other starches.—D. Harvey.

NARAYANA RAO, M., SWAMINATHAN, M. and SUBRAHMANYAN, V. **Nutritive value of safflower seed cake.** *Bull. Central Food Technol. Res. Inst. Mysore*, 1954, 3, 158-159.

Extracted safflower (*Carthamus tinctorius*) seed cake had the following percentage composition: moisture 7.6, ash 4.1, protein 32.1, fat 12.0, Ca 0.075, P 0.62, and vitamin B₁ 0.63 mg. per 100 g. [the rest presumably carbohydrate and fibre].

The addition of 10 per cent. of the cake to a poor rice diet greatly stimulated the growth of rats. The biological value of the protein of the cake was fairly high, but below that of casein.

J. S. Thomson.

NJAA, L. R. and BRAEKKAN, O. R. **Foring av rotter med natriumnitrit og sildemel fremstilt av sild konservert med natriumnitrit. [Feeding rats with sodium nitrite and herring meal made from herring preserved with sodium nitrite.]** *Fiskeridirektoratets Skr. Ser. Teknol. Undersøk.*, 1953, 2, No. 14, pp. 14. English summary.

Literature is reviewed. Rats on a good mixed diet in groups of 2 were given 0.5, 1.0, or 2.0 mg. NaNO₂ by pipette daily for 12 weeks without ill effect; groups of 6 were given 0.1, 0.2, 0.4 or 0.8 per thousand of NaNO₂ mixed in their food, again without ill effect and with a suggestion of better growth with 0.2 per thousand which was not confirmed in a third experiment. In the fourth experiment roughly half of a mixed diet was herring meal prepared from herring preserved with nitrite. The total intake of NaNO₂ over the 70 days of the experiment from one of the samples of herring meal was from 70 to 105 mg.; from the other only 28 to 42 mg. Again growth was

normal and there was no abnormality at post-mortem examination.—I. Leitch.

FÉVRIER, R., GASNIER, A. and VACHEL, J. P. **Valeur alimentaire du tourteau de soja. Influence du traitement thermique. [Nutritive value of soya bean cake. Effect of heat treatment.]** *Ann. Zootech.*, 1952, 1, No. 4, 11-32. [Stat. Recherches Elevage, C.N.R.Z., Jouyen-Josas.]

Three commercial soya bean cakes differing in both origin and treatment were compared in 2 experiments with 3 groups of 4 pigs, in which each group received all 3 types of cake in successive 2-week periods. The cake was the only source of protein in the second experiment, but 4 per cent. meatmeal was given in the first. The value of the 3 cakes was found to be identical, but consumption and growth were greater with the 2 samples extracted by steam than with that subjected to dry heat. Since these samples were all of different grains a third experiment was made with 2 samples of the same origin but after different treatment. The results indicated that the type of treatment affected palatability more than did the origin of the sample.

The same cakes were compared in experiments with rats. In growth experiments the same sample gave the best result in both pigs and rats, but the order of the other 4 samples was reversed. Reasons for this are discussed. It is not possible to use nitrogen balance experiments in adult rats to predict the value of soya bean cake for growing rats or pigs.—D. Duncan.

CONDON, M. Z., JENSEN, E. A., WATTS, A. B. and POPP, C. W. **Effect of autoclaving in presence and absence of gossypol on solvent extracted cottonseed meal.** *J. Agric. Food Chem.*, 1954, 2, 822-826. [S. Reg. Res. Lab., S. Utilization Res. Branch, U.S. Dept. Agric., New Orleans, La.]

A cottonseed meal was produced from prime quality cottonseed by successive extractions with hexane and butanone until the free gossypol content was 0.02 and total gossypol 0.2 per cent. Samples of this meal were heated in layers 1.5 to 2.0 cm. thick in an autoclave at 120° C. for periods up to 120 min. with and without 1 per cent. added gossypol. Estimations of total N, free and total

N.A. and R., January 1955

gossypol, water-soluble carbohydrates, browning, N solubility in 0.5 N NaCl and in 0.02 N NaOH, and P were made and the electrophoretic patterns were recorded. The protein quality index was found by 2-week feeding trials on 10-day-old chickens which had previously been fed on rations low in protein. This index decreased as autoclaving time increased, and was paralleled by a decrease in the amount of N soluble in 0.02 N NaOH. There was no direct correlation with any other chemical test. Meals which had gossypol added during autoclaving were equivalent chemically and nutritionally to control meals autoclaved for the same time.—D. H. Shrimpton.

SUBRAHMANYAN, V., RAMA RAO, G., KUPPUSWAMY, S. and SWAMINATHAN, M. Nutritive value of water chestnut (*Singhara*). *Bull. Central Food Technol. Res. Inst. Mysore*, 1954, **3**, 134-135.

Dried water-chestnut (*Trapa bispinosa*) flour had the following composition : moisture 10.6 g., ash 2.6 g., ether extract 0.56 g., protein 8.0 g., Ca 69 mg., P 343 mg., Fe 2.8 mg. and vitamin B₁ 440 µg. per cent. Rats on a poor vegetarian diet based mainly on water-chestnut flour made substantially better growth than rats on similar poor diets based on wheat, rice, *ragi* or *jowar*. The biological value of the protein of water chestnut was higher than that of wheat.—J. S. Thomson.

1022

DASLER, W. Observations on odoratism (sweet pea lathyrism) in the rat. *J. Nutrition*, 1954, **53**, 105-113. [Dept. Biochem., Chicago Med. Sch., Ill.]

Serum alkaline phosphatase and Hb were not much different in rats fed on a diet containing 50 per cent. sweet pea (*Lathyrus odoratus*) meal and rats fed on a 50 per cent. edible pea meal diet. Adrenal weight was significantly above the control level in male rats but not in females. A gain in adrenal weight per unit bodyweight was significant in both males and females.

The fragility of the skin, the fall in skin weight, the malformation of bones and the haemorrhagic condition of the corium, bones and periosteal tissues found in odoratism suggest a disturbance in collagen metabolism.—A. Hepburn.

LAL, S. B. Effect of argemone oil on monkeys. *Indian Med. Gaz.*, 1954, **89**, 71-74. [Pub. Health Labs., Patna 4, Bihar.]

Eight healthy rhesus monkeys were used. A female weighing 12 lb. given 5 ml. pure argemone oil by stomach tube on 2 successive days showed apathy and failure of appetite after 24 hr. and

died 3 days from the outset. Six males given 5 or 10 ml. daily of mixtures of argemone oil and mustard oil in different proportions showed after about 3 weeks apathy, loss of weight, anaemia, oedema and other signs resembling those of epidemic dropsy, and 3 died; haemorrhagic points were found in the lungs and digestive tract at post mortem. A control given mustard oil remained healthy. There was some evidence that tolerance developed in the survivors and that up to 3 per cent. of argemone oil in the mixture was not lethal.—W. M. Deans.

SOULAIRAC, A. and SOULAIRAC, M. L. Effets du groupement sur le comportement alimentaire du rat. [Effect of grouping on feeding behaviour in the rat.] *C.R. Soc. Biol.*, 1954, **143**, 304-307. [Lab. Psychophysiol., Sorbonne.]

Adult male rats were caged individually for 26 days, then in pairs for 58 days and finally in threes for 65 days. They received a standard diet, a 10 per cent. glucose solution and water to appetite.

When the rats were placed in pairs total food consumption and energy intake increased and glucose consumption fell, but the differences became significant only after 20 days. Grouping in threes further increased food consumption and decreased that of glucose, but energy intake did not increase; the changes were greatest in the first 27 days. The weight of the rats reflected the changes in intake of stock diet.—D. Duncan.

RUEGAMER, W. R., BERNSTEIN, L. and BENJAMIN, J. D. Growth, food utilization, and thyroid activity in the albino rat as a function of extra handling. *Science*, 1954, **120**, 184-185. [Veterans Admin. Hosp., Denver, Colo.]

Of 42 weanling male albino rats fed on the same diet, half were petted and handled individually for about 10 min. daily, the others were touched as little as possible. After 5 weeks the rats were injected intraperitoneally with 50 μ C. of ^{131}I and 24 hr. later were killed.

There was no statistically significant difference between the amounts of food consumed by the 2 groups, but the handled animals showed a mean weight gain of 122.8 g., compared with 108.1 g. for the unhandled group, a difference statistically significant at the 0.001 level of confidence. The food consumed per g. weight gain was on the average 4.82 g. for the handled group and 5.49 g. for the unhandled, again significant at the 0.001 level. There was no significant difference in body composition or in organ weights. The unhandled rats excreted more faecal pellets than the handled ones. Subsequent experiments confirmed that early handling resulted in greater weight, increased skeletal length and better food utilisation. The thyroids of unhandled rats were more active than those of handled rats. It is suggested that this greater thyroid activity may be partly responsible for poorer growth and food utilisation.

ENDERS, A. Die Wachstumsfähigkeit von Ratten nach calorischer Unterernährung und bei chronischen Vergiftungen. [Growth capacity of rats after caloric underfeeding and chronic poisoning.] *Arch. exp. Pathol. Pharmacol.*, 1954, 222, 555-561. [Pharmakol. Inst., Univ. Freiburg i. B.]

Verzár (*Helv. med. Acta*, 1940-41, 7, Suppl. VI) by restricting the allowance of food kept rats at an average weight of 50 g. for 5 months. Thereafter when food was not restricted the rats grew to weights of 450 g. (males) and 250 g. (females), designated giant growth. This experiment was repeated with albino or brown and white rats from the mixed stock colony of the Institute. The diet was oat flakes 500 g., cod liver oil 15 g., dried yeast 30 g., dried milk 100 g., McCollum salt mixture 15 g. and water 1 litre; mixed and heated to boiling-point. Once or twice a week lettuce or dandelion leaves were given. The rats were weighed daily and the allowance of food was adjusted to maintain weight at 50 g. Of 20 males and 20 females, 9 females and 6 males survived for 6 months. They were then given food to appetite and 6 months later weighed on the average females 202 and males 315 g. Controls averaged 205 and 303 g.

Later, 6 males and 6 females survived to 12 months and 3 females and 4 males to 15 months. They were then fed to appetite for 8 months and weighed after 12 months' underfeeding 194 and 298 g., and after 15 months' underfeeding 178

and 319 g. Three of the females from the 12-month lot were mated with normal males and produced normal litters.

In a further experiment 12 female rats were given 15 g. food daily for a year and then the 9 survivors weighed on the average 114 g., and after 8 months' unrestricted feeding 211 g. In another, rats were castrated at 4 to 5 weeks of age and similarly treated. There was no impairment of growth capacity and no giant growth. Nor did chronic poisoning with Hg, colchicine or ethylurethane, with characteristic pathological changes, interfere with growth.—I. Leitch.

WILHELMJ, C. M., MILANI, D. P., MEYERS, V. W., GUNDERSON, D. E., SHUPUT, D., RACHER, E. M. and MCCARTHY, H. H. An analysis of the stress of realimentation with carbohydrate or protein following prolonged fasting. *J. Lab. Clin. Med.*, 1954, 43, 888-896. [Dept. Physiol., Sch. Med., Creighton Univ., Omaha, Nebr.]

Of 9 dogs which had been fasted 5 were given a high-protein diet of raw horsemeat and 4 a high-carbohydrate diet of biscuit meal or rice. The group of 5 animals were again fasted and were then given the high carbohydrate diet followed by an isocaloric high-protein diet; 3 new dogs were added to the experiment during this part. Stress was estimated from capillary resistance, eosinophil and total leucocyte counts.

During fasting there was a rise in capillary resistance and a decrease in circulating eosinophils. The high-carbohydrate diet maintained these fasting effects; the high-protein diet caused a rapid return to normal values when given either to the fasting animal or after the high-carbohydrate diet. The effect of the high-carbohydrate diet persisted for 71 days in one animal, but 3 animals showed a slow spontaneous return to normal while on the high-carbohydrate diet in 50 to 60 days; after spontaneous recovery cortisone and ACTH caused, respectively, complete and partial return of the capillary resistance and eosinophil levels to the high-carbohydrate values. Systolic blood pressure and pulse rate showed similar reactions during spontaneous recovery and administration of cortisone, suggesting that spontaneous recovery may be associated with depletion of the pituitary-adrenal hormones. It is also suggested that the stress engendered in fasting animals by re-alimentation with high-carbohydrate diets is associated with hyperactivity of the pituitary-adrenal system, which is counteracted by isocaloric high-protein diets.—G. F. Garton.

KÖHN, K. Experimentelle Untersuchungen an Ratten zur Frage der Beeinflussbarkeit des

N.A. and R., January 1955

Lymphgewebes durch die Art der Nahrung sowie durch Hunger. [Experimental investigation with rats of the possibility of influencing the lymphoid tissue through the kind of food or through starvation.] *Ztschr. ges. inn. Med.*, 1954, 9, 195-199. [Pathol. Inst., Berlin-Spandau.]

Of 60 rats weighing from 160 to 260 g., 12 received a normal diet; 18 received an "acid" diet of oats and brown bread with a solution of HCl to drink, and half of these received once or twice a day 1 ml. of 2 per cent. NH_4Cl solution; 15 received an "alkaline" diet of carrots, peelings, white bread and milk, and 10 of these received once or twice daily 1 ml. NaHCO_3 solution; 15 were starved with plenty of water, and 8 of them were given NaHCO_3 . At intervals the pH of the urine and the blood picture were recorded, and at the end the alkali reserve of the blood was measured. After 2 to 3 weeks the rats were killed and the spleen and lymph nodes were examined histologically.

The rats on normal diet maintained weight, those on acid and alkaline diet lost a little, and the starved animals lost 45 per cent. of their weight. The pH of the urine was from 6.5 to 7.5 with normal diet, from 5 to 6 with acid diet, from 7 to 8 with alkaline diet and prolonged treatment with carbonate, from 5.5 to 6.5 with starvation, and from 6.5 to 8 with starvation and alkali. The alkali reserve was reduced in the rats with acid diet and with starvation, unchanged with starvation and alkali, and slightly raised with alkaline diet. With acid diet and starvation without alkali the leucocytes in the blood increased at the cost of the lymphocytes; with other treatments there was no change. Such changes as appeared in the histology of the spleen and lymph nodes were the same with acid and alkaline diets. The spleen and lymph nodes lost weight under starvation more severely than the rest of the body.

CLARK, H., GRAHAM, P. and MUIRHEAD, E. E. Effect of diets on the anemia, azotemia and

Vol. 26, No. 1

survival of bilaterally nephrectomized rabbits. *J. Lab. Clin. Med.*, 1954, 43, 113-118. [Dept. Pathol., Southwestern Med. Sch., Univ. Texas, Dallas.]

The techniques of nephrectomy and of estimation of blood volume, haematocrit and blood urea were described by Muirhead *et al.* (*J. Lab. Clin. Med.*, 1952, 39, 505). Different fluid diets were given after the removal of the second kidney, namely, a high-protein high-carbohydrate mixture, a fat emulsion, glucose solutions supplying 2.8 or 30 Cal. per kg. daily, and water only. Unoperated control rabbits received either the fat emulsion or stock diet. All received a vitamin mixture.

The mean haematocrit fell in all rabbits after kidney removal; the greatest falls were in the groups receiving fat emulsion or high-glucose diets, and the smallest in those receiving protein. Total blood volume fell slightly in all after kidney removal and considerably in those receiving fat emulsion. Plasma volume was unchanged or fell slightly. Plasma chloride concentration fell, except in the rabbits receiving protein. Red blood cell volume fell, especially in the operated group receiving fat emulsion, and it also fell in unoperated rabbits on this diet. Blood urea concentration rose steeply in all operated rabbits, but least on the high glucose intake. Rabbits fed on protein survived only an average of 3.8 days; those on glucose survived longest, 6.7 days on the high intake and 7.1 days on the low.

It is concluded that a high protein intake was detrimental and that glucose exerted some protective effect against the uraemia.—D. Duncan.

CHRISTENSEN, F. and DAM, H. Alimentary production of gallstones in hamsters. 3. *Acta physiol. scand.*, 1954, 31, 75-82. [Dept. Biochem., Polytech. Inst., Copenhagen.]

For earlier work see Abstr. 4874, Vol. 23.

The basal diet was the synthetic one already described. A large number of cereal and legume seeds and a type of yeast as well as some extracts of these were tested for their ability, as additions to or as replacements of part or all of the sucrose, to prevent gallstone formation. Soya beans and yeast were particularly active, hempseed less.

Two other diets, one a commercial chicken mash and the other a similar synthetic diet with crude casein 25, sucrose 63.1, salt mixture 4.0, vitamin mixture 0.5, choline chloride 0.4 and lard 7.0 per cent., did not cause gallstone formation. It is thought that these may contain a protective organic substance insoluble in fat. The study is being continued.—D. Harvey.

NAFTALIN, J. M. Weaning age and dietary liver necrosis in the rat. *J. Pathol. Bacteriol.*, 1954, **67**, 335-339. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]

Young rats received from their 38th day of age a low-protein diet containing either casein 8 and brewer's yeast 3 per cent. or brewer's yeast 18 per cent. as source of protein. Littermates were weaned at different ages, i.e., 17, 19 or 20 and 25 days.

The difference in survival time between rats weaned at 17 and those at 19 days was not significant, but rats weaned at 25 days survived significantly longer. The incidence of liver necrosis in the last group was significantly lower in 2 out of 3 experiments.

Differences in the capacity of several breeds of casein to produce liver necrosis are reported.

D. Duncan.

1037

SMITH, D. E. and TYREE, E. B. Influence of X-irradiation upon body weight and food consumption of the rat. *Amer. J. Physiol.*, 1954, **177**, 251-260. [Div. Biol. Med. Res., Argonne Nat. Lab., Lemont, Ill.]

In groups of from 6 to 19 rats total body exposure to X-rays in single doses of between 25 and 10,000 r resulted in immediate anorexia and weight loss, the magnitude and duration of which were dependent on the intensity of radiation. Recovery from the weight loss due to anorexia was also a function of the dose. The rates of weight loss of the young rats were similar to those of the older rats. Exposure of almost any portion of the body was also immediately followed by anorexia and loss of weight; the duration and degree of the changes depended on the part of the body exposed. The parts in order of increasing response to 800 r were hind legs and tail; head, chest, stomach and spleen; abdomen, intestine and entire body except head.—G. F. Garton.

1039

PAGET, G. E. Exudative hepatitis in guinea-pigs. *J. Pathol. Bacteriol.*, 1954, **67**, 393-400. [Dept. Pathol., Univ. Manchester.]

Outbreaks of disease occurred in 1951 in 2 large colonies of guinea-pigs in the Manchester area; each colony contained about 300 animals, of which about half died. There was no transfer of staff or stock between the colonies and the only common feature was that both used a commercial form of the diet described by Bruce and Parkes (Abst. 138. Vol. 17). When the diet was abandoned the disease disappeared. Rabbits were not affected. Only certain batches of the commercial diet appeared to be implicated.

The animals became sluggish and had rough coats and sometimes patchy loss of hair. There was a characteristic pad of oedematous tissue on the abdominal wall, and sometimes ascites. Death occurred in a few hours. Antibiotics were of no value. At post mortem over 80 per cent. of the animals had oedema or serous effusions. About 75 per cent. had greatly enlarged mesenteric lymph nodes, white and fleshy, especially the ileocaecal group. The spleen was slightly enlarged and red. The liver was pale but appeared little altered macroscopically, though histologically there was gross abnormality; the portal tracts and parenchyma were infiltrated with plasma cells and lymphocytes, the portal tract lymphatics were dilated, and there was striking dilatation of the liver-cell columns, sometimes giving a honeycomb appearance to the tissue. There was no jaundice or increase in serum bilirubin.

It was not possible to reproduce the disorder in other guinea-pigs fed on the commercial diet. A deficiency is postulated, but the etiology of the disorder is unknown.—D. Duncan.

MAYER, J., MARSHALL, N. B., VITALE, J. J., CHRISTENSEN, J. H., MASHAYEKHI, M. B. and STARE, F. J. Exercise, food intake and body weight in normal rats and genetically obese adult mice. *Amer. J. Physiol.*, 1954, **177**, 544-548. [Dept. Nutrit., Harvard Sch. Pub. Health, Boston, Mass.]

A treadmill is described which is suitable for exercising rats and mice.

When mature, normal rats were exercised for 20, 40 or 60 min. daily they consistently consumed less food than when they were not exercised, and their weight decreased correspondingly. With daily exercise lasting 2 hr. or more, food intake increased linearly above the initial amount with duration of exercise, though bodyweight was maintained slightly below that reached after 60 min. exercise daily. When exercise exceeded 6 hr. the results were complicated by extreme fatigue.

N.A. and R., January 1955

The mice were adult, genetically obese animals weighing on the average 52 g. and non-obese controls weighing 22 g. Half the mice were exercised for 1 hr. daily, divided between morning and afternoon. Exercise increased the food intake of non-obese mice slightly and they maintained their weight. Obese mice without exercise ate on the average 4.5 g. food daily and gained in 45 days 14.7 g., while those made to exercise increased their food intake to 7.0 g. daily, but gained only 9.2 g. in bodyweight during the experiment.

SOGNNAES, R. F. and SHAW, J. H. Experimental rat caries. 4. Effect of a natural salt mixture on the caries-conduciveness of an otherwise purified diet.

SHAW, J. H. and SOGNNAES, R. F. 5. Effect of fluorine on the caries-conduciveness of a purified ration. *J. Nutrition*, 1954, 53, 195-206; 207-214. [Harvard Sch. Dent. Med., Boston, Mass.]

For earlier work in this series see Title 3429, Vol. 18 and Absts. 5297, Vol. 19 and 4759, Vol. 18.

4. The diets given to 239 rats were the basal caries-producing ration of purified foods used by Shaw (Abst. 2317, Vol. 17) and the same ration with the mineral mixture component replaced by an equivalent amount of the ash derived from Purina laboratory chow. The animals were in 2 main groups of 139 from which all major salivary glands had been removed at weaning and 100 untreated normal rats. Feeding was arranged so that during pregnancies and lactations up to their fourth, dams received either the basal or the experimental diets only or a combination of these, the change from basal to experimental being made at the time of birth or of weaning of the litter. Except for the fourth litters which received the

experimental diet, all litters were given the basal ration. At 7 months of age the young were killed and their teeth were examined.

No significant difference was found in the rate of growth of rats on the 2 diets. Although it contained all known essentials the purified ration gave rise, in the normal animals, to a greater incidence of caries than did the one with the ash of laboratory chow. The protection which that ash conferred may have resulted from the presence of trace elements. In the desalivated rats changing the type of mineral mixture had no effect on the incidence of caries.

5. In experiments on a similar plan the same caries-producing diet was used and the effects were studied of adding to it 6 or 25 p.p.m. F as NaF. There was little protective effect against caries, nor could the absence of caries in earlier work with natural diets be attributed to their F content. While the influence of F cannot be gainsaid, the evidence is taken to support the view that it is minerals other than F, or the ratios existing between them, which determine differences in the incidence of caries.—D. Harvey.

NIKITIN, S. A. and BUGAEVA, M. G. Eksperimental'nyi karies u belykh krysy. [Experimental dental caries in white rats.] *Stomatologiya*, 1954, No. 1, 9-17. [Dept. Pathophysiol., Sci. Res. Inst. Stomatol., Odessa.]

In the first experiment 47 mice weighing 10 to 12 g. were fed on a carbohydrate-rich diet of whole rice 55, sucrose 24, dried powdered milk 15, sunflower oil 5 and salt 1 per cent. There were 50 controls fed on bread, oats and milk. The experiment lasted 100 days. In the second experiment 12 white rats were on a "caries-producing" diet of wheat 50, sugar 32, vegetable oil 15 and salt 3 per cent. The 13 controls had bread, milk, oats, a small amount of cooked meat and cod liver oil. In neither experiment did the animals show any trace of dental caries.

In the third experiment rats received a diet containing all the necessary organic and inorganic elements, but in an unusual form for these particular animals. The diet consisted of curds washed in tap water and dried 24, sugar 67, sunflower oil 5, salt mixture 4 per cent., bread, as an appetiser, 2 or 3 g. per rat and 1 polyvite tablet per week for the whole group. Caries of the enamel and dentine occurred in rats fed on this diet during the last days of pregnancy and continued during lactation and after. Rats brought up on this diet and continued on it for 3 to 10 months developed surface caries. The second generation of rats, bred from rats brought up on a "caries" diet and continued on this diet, developed caries of all the molars at from 3 to 4 months. When this second generation

and the mother were fed on a normal diet immediately after birth, no caries developed during the same time. On the other hand, keeping the female rat on normal food during most of pregnancy did not affect the onset of 100 per cent. caries in her progeny when they and the mother were fed on a caries-producing diet, the pregnant rat being started on it 1 or 2 days before parturition.

SHAW, J. H. The effect of carbohydrate-free and carbohydrate-low diets on the incidence of dental caries in white rats. *J. Nutrition*, 1954, 53, 151-162. [Harvard Sch. Dent. Med., Boston, Mass.]

In 4 experiments 19 groups of rats were given one or more of 5 diets. The basal caries-producing diet was a mixture of sucrose 67, casein 24, maize oil 5, salts 4, and liver 2 parts with vitamins added. Two variants were, except for traces, free from carbohydrate, sucrose replaced in one mostly by casein and in the other mostly by lard; in the third, ground maize starch was substituted for sucrose and in the fourth all but about 6 per cent. of the sucrose was replaced by casein or lard. In 3 of the 4 experiments the rats were desalivated.

On the 2 carbohydrate-free and on the low-carbohydrate diets caries did not develop even after desalivation of the rats and after as long as 2 years. Transfer of the animals to or from the basal diet resulted in corresponding appearance or arrest of lesions. It is concluded that a source of carbohydrate is necessary both for the initiation and for continued development of caries.

MUHLER, J. C. and SHAFER, W. G. Experimental dental caries. 2. Effect of desalivation on dental caries and castration and desalivation on fluorine storage in the rat. *J. Dent. Res.*, 1954, 33, 346-356. [Dept. Chem., Indiana Univ., Bloomington.]

In 8 groups of rats, 4 of each sex, the treatments were (1) desalivation, i.e., removal of submaxillary and sublingual glands and of at least three-quarters of the parotids, (2) desalivation and giving, as stannous fluoride, 25 μ g. F per ml. drinking water, (3) control and (4) control with F in the same form as in (2). Operations were at ages between 30 and 36 days and all animals were given a caries-producing diet until the age of 140 days, when they were killed.

Desalivation resulted in an increase in the incidence of caries which was relatively greater in females than in males; the inclusion of F diminished this effect in both sexes. The effect on growth was as already reported (Abst. 4890, Vol. 24) and F did not alter it. Desalivation did not influence the weight of testes, but did reduce the weight of the uterus by producing generalised atrophy. Changes in adrenals were not consistent except for a thickening of the zona glomerulosa which occurred in females. There was no histological change in thyroid, pancreas or epiphyses of long bones.

The giving of F greatly increased the amount stored in the skeleton, but did not affect the process of calcification as judged by the ratio of Ca : P in the femurs.—D. Harvey.

1048

MUHLER, J. C. and SHAFER, W. G. Experimental dental caries. 4. The effect of feeding desiccated thyroid and thiouracil on dental caries in rats. *Science*, 1954, 119, 687-689. [Dept. Chem., Univ. Indiana, Bloomington.]

About 175 Sprague Dawley rats on a stock cariogenic diet (Muhler *et al.*, *J. Amer. Dent. Assoc.*, 1953, 46, 290) were divided into 6 groups, which were given desiccated thyroid, from 10 to 60 mg. daily, with or without 20 μ g. F as NaF per ml. in their drinking water, or 0.1 per cent. thiouracil in the diet, with or without 20 μ g. F per ml. water, or the F alone, or no supplement. After 145 days they were killed, caries was evaluated, and F, Ca and P were estimated in femurs.

Growth was not affected by thyroid or F, but was depressed by thiouracil. None of the supplements affected calcification of the skeleton. The concentration, but not the absolute amount, of F was greatest in those given thiouracil and F; thyroid had little effect on either. Thyroid was as effective as F in reducing dental caries and the 2 combined had a greater effect than either singly. Thiouracil increased caries and the further addition of F was without effect, confirming that there is some connection between thyroid activity and caries in the rat.—W. M. Deans.

CONSTANT, M. A., SIEVERT, H. W., PHILLIPS, P. H. and ELVEHJEM, C. A. Dental caries in the cotton rat. 14. Further studies of caries production by natural diets with especial reference to the role of minerals, fat, and the stage of refinement of cereals. 15. The effect of tooth maturity and minerals on caries production by semi-synthetic diets. *J. Nutrition*, 1954, 53, 17-27; 29-41. [Dept. Biochem., Univ. Wisconsin, Madison.]

14. For earlier work see Absts. 4619, Vol. 16; 2663, Vol. 22. In all, 34 sets of data, evaluated

N.A. and R., January 1955

by the methods originally described (Abst. 3499, Vol. 14), are reported.

The basal diets were one of finely ground oatmeal 50, dried whole milk powder 32, and sucrose 18 per cent. and 3 variants in which the amount of oatmeal was unaltered but which contained cereal and dextrin (CD), cereal, dextrin and sucrose (CDS) and cereal, dextrin, sucrose and fat (CDSF). In weanling cotton rats the incidence of caries was lowest on the first and highest on the fourth diet; substitution of casein and dextrin for milk powder resulted in severe tooth decay; the inclusion of maize oil afforded no protection. Addition of CaCO_3 or Na_2HPO_4 to the CDSF diet greatly reduced the incidence and extent of caries; without Ca a mixture of basic salts also diminished the incidence, but with Ca the effect was much greater. When the CDSF diet was not given until 1 month after weaning tooth decay was greatly reduced.

For study of the effects of varying the source of fat a diet of equal parts of oatmeal and dried whole milk powder and containing 14 per cent. fat was compared with others in which dried skimmed milk and fats replaced the dried whole milk. Although the first of these contained no sucrose the incidence of caries was moderate when it was given. With maize oil 7 per cent. and dried skimmed milk powder there was good protection against caries.

The influence of processing the oatmeal was examined in experiments with diets containing whole oats, groats before or after steaming, rolled oats and mixtures of groats with hulls or with the ash of hulls. The incidence of caries was greatest after removal of the hulls. The addition of ash had no effect on the production of caries.

15. Experiments were made over several years and 52 sets of data were obtained. The basal diet contained casein 24, sucrose 67, salt mixture 4 and maize oil 5 per cent. with vitamins added. The experiments are in 3 groups.

In the first set a decrease in Ca content increased the incidence of caries. Delay in introducing the cariogenic diet until the cotton rats were 8 weeks old reduced both incidence and severity. In the second set mixtures of basic or acidic organic salts and of acidic inorganic salts had no protective action against caries; only mixtures of basic inorganic salts prevented tooth decay. In the third set attempts were made to modify the effects of the low-Ca, high-sucrose diet. Addition of maize oil to give 15 per cent. fat or reduction of the sucrose to 20 per cent. by replacing it with dextrin made no change. Addition of lysine or tryptophan or a combination of these did not reduce the incidence, but the source of protein had some effect. Incidence of caries was slightly less with albumin and considerably less with fibrin instead of casein.—D. Harvey.

SEAGRAN, H. L., MOREY, D. E. and DASSOW, J. A. The amino acid content of roe at different stages of maturity from the five species of Pacific salmon. *J. Nutrition*, 1954, 53, 139-149. [Fish. Prod. Lab., U.S. Fish and Wildlife Serv., Ketchikan, Alaska.]

There was little variation, either between individuals or between species, in the essential amino-acid content of salmon roe at the same stage of maturity; very immature roe contained more threonine and less histidine, isoleucine, leucine, lysine, methionine, phenylalanine and valine than mature. Average values for mature salmon roe, expressed as per cent. of protein calculated to 16 per cent. N, were arginine 7.2, histidine 2.7, isoleucine 7.2, leucine 9.9, lysine 8.8, methionine 2.9, phenylalanine 4.8, threonine 5.9, tryptophan 0.9 and valine 7.2.—C. Warner.

BONDI, A. and SPANDORF, A. The action of the digestive enzymes of the carp. *Brit. J. Vol. 25, No. 1*

Nutrition, 1954, 8, 240-246. [Lab. Animal Nutrit., Agric. Res. Stat., Rehovoth, Israel.]

To investigate the digestive activity of the carp, which lacks a stomach, extracts from the pancreas and intestine were incubated with purified casein, peptone, meat, fish, soya bean and groundnut meals, starch, maltose and wheat bran. Protein and carbohydrate digestion were measured by the production of amino-acids and reducing sugar, respectively.

The digestion of casein by the pancreatic extract reached 50 per cent. at 38° C. and pH 7.0. The meal preparations were digested to a similar extent. Intestinal extract digested only 12 per cent. of casein, but in the presence of pancreatic extract 82 per cent. Peptone digestion was 62 per cent. with intestinal extract and only 26 per cent. with pancreatic extract; the extracts together increased the initial rate of digestion, but 62 per cent. was the maximum obtained.

More than 90 per cent. of starch was digested by pancreatic extracts, and digestion of maltose was quicker. Bran was digested to the same extent

over a longer time. Intestinal extracts did not liberate reducing sugars from starch, and maltose was only 30 per cent. digested after 3 days. The intestine had evidently a smaller maltose activity than the pancreas, the opposite being true in mammals.—A. Hepburn.

- LECLERCQ, J., MAGIS, N. and REY, C. Sur les besoins nutritifs du *Gnathocerus cornutus* F. (Coléoptère, Ténébrionide). Recherche de l'optimum glucidique et de l'optimum protéidique dans un régime alimentaire artificiel. [Nutritive requirements of *Gnathocerus cornutus*, F. (Coleoptera, Tenebrionidae). Carbohydrate and protein optima in an artificial diet.] *Arch. internat. Physiol.*, 1954, **62**, 264-271. [Inst. Léon Fredericq, Univ. Liège.]

Larvae of the broad-horned flour beetle *Gnathocerus cornutus* were reared in groups of 20 in containers with 20 g. diet at 30°C. and 60 to 70 per cent. relative humidity. The 7 diets tested included whole wheat flour with a water content of 12 to 14 per cent.; dried baker's yeast; and 5 combinations of casein, glucose and yeast with 6 to 8 per cent. water content.

Larval mortality was least on wheat flour and greatest on diets rich in glucose and poor in protein. Development was quickest on wheat flour and on yeast and slowest on low-protein diets, and the variation in time was least on the 2 natural media. The mean weight of nymphs was greater

on wheat flour than on the other diets. There was not much difference in value between the synthetic diet containing no casein and those with 15 or 45 per cent.

Gnathocerus cornutus has a high protein tolerance and a low sugar tolerance and differs in these respects from other Tenebrionidae so far studied.

DIET

REQUIREMENTS

1058

- ALMQUIST, H. J. A fallacy in the analysis of nutritional requirement data. *Arch. Biochem. Biophys.*, 1954, **50**, 503. [The Grange Company, Modesto, Calif.]

In many examples of the analysis of nutritional requirement data, the law of diminishing returns is closely adhered to. This implies that in these cases biological response increases linearly with the logarithm of the level of some nutritional factor. For this reason it is incorrect to compare the response corresponding to a given change in the factor at different levels of that factor. One should compare the response corresponding to a given percentage change in level of the nutritional factor in order to obtain a uniform test at all levels.—A. W. Boyne.

Vol. 25, No. 1

An improvement in lactation performance of women in the first week after parturition was attained during the 5 years from 1947 to 1951 at the St. Pölten Hospital. On discharge from hospital 70 per cent. of mothers had enough or more than enough milk, 28 per cent. had insufficient milk, and 2 per cent. could not feed their infants. Excess milk was collected by breast pump for infants who could not be breast fed wholly or in part by their mothers. Problems of breast milk supply for newborn infants are discussed with reference to modern methods of handling.—A. M. Copping.

- CROSSE, V. M., HICKMANS, E. M., HOWARTH, B. E. and AUBREY, J. The value of human milk compared with other feeds for premature infants. *Arch. Dis. Childhood*, 1954, **29**, 178-195. [Premature Baby Unit, Sorrento Maternity Hosp., Birmingham.]

Infants weighing less than 4 lb. at birth were grouped according to birthweight and in each group babies were allocated in rotation to the five test diets: 1 human milk; 2 low-protein evaporated cow's milk mixture; 3 high-protein dried half-skimmed cow's milk mixture; 4 human milk with sweetened casein hydrolysate and 5 evaporated cow's milk with sweetened casein hydrolysate. Fat content was kept at 1.6 per cent. in the cow's milk mixtures. The energy values of all the diets were adjusted to 20 Cal. per fluid oz. by varying the amount of sugar in the cow's milk mixtures and by slight dilution of human milk before addition of casein hydrolysate. All diets were given diluted for the first 7 to 10 days. Supplements of vitamins, Ca, P and Fe were given to all babies.

In all weight groups infants given diet 3 regained birthweight in the shortest time. Except for the

babies in the 2 to 2½ lb. group, infants in the groups given diet 5 regained birthweight in approximately the same time as the corresponding groups given diet 3. The groups given diet 1 took somewhat longer than did those on diet 3 and the slowest progress was in infants on feeds 2 and 4, especially the smaller ones. Infants on diet 3 also made the most rapid gains subsequently, but because of the occurrence of oedema their superior gains as compared with group 1 were attributed in part to greater retention of water.

As judged by Hb values diet 2 was inferior to the other diets. During stay in hospital the least infection occurred in infants given diet 1, followed closely by those given diet 3.

Curves for serum proteins were not affected by diet except that in the smallest babies the lowest values for total proteins were found in those given diets 2 and 5; the lowest albumin values were in those on diet 2.

Some observations on the incidence of rickets and retrolental fibroplasia are made.

From 4½ lb. weight, which was the stage of discharge from hospital, there were 3 feeding groups, breast milk or low-protein full-cream dried milk or high-protein half-skimmed dried milk mixtures. At the end of 6 months the highest average weight was for the 12 in the first group and no major infection or death had occurred; there were 3 cases of infections and no death among 30 infants in the second, and 14 cases of infections and 5 deaths among 110 in the third. At 1 year of age all breast-fed infants were alive but 1 in the second and 9 in the third group had died.

In the opinion of the authors human milk is the best food for premature babies.—F. C. Aitken.

1065

SYDOW, G. v. and FAXÉN, N. **Breast or cow's milk as infant food. Discussion on the methods of comparison.** *Acta paediat.*, 1954, 43, 362-367. [Child Dept., Länslasarett, Sundsvall, Sweden.] French, German and Spanish summaries.

In comparative studies of breast milk and cow's milk as food for infants the groups should be identical in all respects other than feeding and the supply of food should be equally free or equally limited to both. Such a comparison may be made most easily in a children's home. A small investigation of 48 infants is described to illustrate the method. Alternate infants were given collected, sterilised breast milk or cow's milk and all were nursed together under equal risks of infection. The number of days with a rise in infant temperature was higher in the cow's milk than in the breast milk group.—F. C. Aitken.

ALLÚE DE HORNA, A., IBARZ, A. and MONNE, R. **Leche entera acidificada. La absorcion de grasa y su influencia en los procesos inmunarios. [Acidified whole milk. Fat absorption and its influence on the processes of immunisation.]** *Rev. española Pediat.*, 1954, 10, 327-354. [Plaza de Prim., 3, Tarragona.] French, English and German summaries.

In 5 more or less healthy infants fed on acidified whole milk with 17 per cent. fat the coefficient of absorption of fat was always more than 80 per cent. and in 50 per cent. of analyses more than 90 per cent. The intake varied from 13.6 to 35.7 g. fat and on only one occasion was more than 4 g. excreted. In 6 sick children the absorption of fat was poorer, but it improved steadily as they recovered. Nearly all the children in both groups had major or minor infections at intervals before they received the experimental diet, and it is considered that a high coefficient of fat absorption was closely related to resistance to infection.

D. Duncan.

1069

SUÁREZ, M. and VELASCO, J. A. **Estudios sobre absorcion de grasa en el lactante. 1. Comunicacion. Absorcion de grasa en la alimentacion con la leche en polvo acidificada. [Studies on fat absorption in the infant. 1. Fat absorption in feeding with acidified powdered milk.]** *Rev. española Pediat.*, 1954, 10, 355-368. [Cat. Paediat. Puericolt., Univ. Santiago de Compostela.] French, English and German summaries.

In 8 infants aged from 4 to 12 months, some with digestive disorders, acidified whole milk powder (Pelargon) gave better fat absorption than fresh or condensed milk. The coefficient of fat absorption was very low in infants with diarrhoea, but rose progressively during recovery. The powdered milk preparation also provided a higher protein intake than condensed milk and about twice as much as human milk. Its high nutritive value is considered to maintain a high resistance to infection.—D. Duncan.

1071

WELBURN, H. **The danger period during weaning among Baganda children.** *East African Med. J.*, 1954, **31**, 147-154. [Child Welfare Clin., Mengo District, Uganda.]

Baganda babies are weaned at about 14 or 15 months, but from about 6 months the lactation is insufficient and the only supplement is cooked plantain. Heights and weights were recorded for Baganda children, most of whom lived in villages. Of those aged from 6 months to 3 years, 30 per cent. had chronic respiratory infections and 46 per cent. had signs of kwashiorkor. Heights have as yet been recorded continuously only for 8 months. Weights from 1 to 18 months were recorded for 102 children, of whom 14 had well educated parents. Of the 14, rate of weight increase was good throughout in 7, good at first but less good after 6 months in 6, and poor throughout in 1. For the 88 from ordinary homes, the corresponding figures were 12, 64 and 12. Forty-nine of those who did well at first were followed for 2 years; 9 had infections and their weight increase continued to be unsatisfactory; 7 gained well and made up lost ground, and the remaining 33 continued to gain but always at a level below the normal. Infections had a worse effect on the weight increase of children already gaining badly because of malnutrition, and such children were more liable to infections. Severe whooping-cough often appeared in the case history of patients with kwashiorkor.—E. M. Hume.

BRANSBY, E. R. and FOTHERGILL, J. E. **The diets of young children.** *Brit. J. Nutrition*, 1954, **8**, 195-204. [Minist. Health, Savile Row, London, W.1.]

The diets of 461 children aged between 6 months and 5 years and living in 10 localities in England were surveyed in April 1951. A record of food

consumption was kept by the mother for 1 week; the method was similar to that described by Widdowson (Abst. 3858, Vol. 6) and Beltram and Bransby (Abst. 4041, Vol. 20). During the week of the diet survey a social survey was made also.

The average consumption of all principal foods except milk, sugar, green and other vegetables, soup and gravy increased with age. The average daily energy intake rose from 1080 Cal. for children under 1 to 1730 Cal. for children aged 4; for nutrients corresponding values were protein 38 and 51 g., fat 46 and 76 g., Ca 0.97 and 0.76 g., Fe 6.7 and 9.0 mg., vitamin A 2160 and 2380 I.U., vitamin B₁ 0.58 and 0.77, nicotinic acid 2.7 and 6.6, riboflavin 1.18 and 1.03 and ascorbic acid 14.2 and 28.2 mg. Boys, children in large families, children whose mothers went out to work and children in lower income groups tended generally to have intakes of energy and nutrients above average; girls, only children and children whose mothers did not go out to work tended to have nutrient intakes below average. The weight of food eaten and the intakes of energy and of all nutrients were either high or low; a high intake of some nutrients was not offset by low intakes of others. The average intakes of energy, Fe, vitamin A, vitamin B₁, riboflavin, and ascorbic acid by children aged 6 to 12 months and 1, 2, 3 and 4 years exceeded the British Medical Association's recommendations.

Other intakes were below those recommended, that of protein by children of 2 to 4 years by 9 to 18 per cent., of Ca by children of 1 to 4 years by about 25 per cent.; that of nicotinic acid for children under 1 year and at 1 year of age by 15 and 5 per cent., respectively.—G. F. Garton.

1073

INTENGAN, C. L., ALEJO, L. G., CONCEPCION, I. and SANTIAGO, L. C. **A biochemical evaluation of the UNICEF school lunch program given to malnourished school children of San Andres elementary school, Manila.** *Acta med. philipp.*, 1952-53, **9**, 181-196. [Foods and Nutrit. Biochem. Div., Inst. Nutrit., Dept. Health, Republic Philippines.]

Hb, protein, ascorbic acid, riboflavin, vitamin A and carotene in the blood, and riboflavin and vitamin B₁ in the urine, were measured in 200 children aged from 7 to 13 years after half of them had received daily for a year a special school lunch which was part of the UNICEF programme. The lunch supplied about one-third of their daily energy needs and included milk and undermilled rice. In the children having the lunch higher values were found for Hb, protein and riboflavin in the blood and for riboflavin in the urine. Vitamin B₁ in the urine was considered to be low and was only 10 per cent. higher in those having the

lunch. Serum vitamin A and carotene values were low in all the subjects and were not higher with the school lunch. All vitamin C values were satisfactory. The chief deficiency in the diet appeared to be of vitamin A, and increased use of milk and green and yellow vegetables is recommended.—A. M. Copping.

DE SEGURA, R. M. Consumo de leche y derivados en el estudio de la anamnesis alimentaria de 137 embarazadas. [Consumption of milk and milk products in diet histories of 137 pregnant women.] *Rev. Asoc. argent. Dietologia*, 1953, **11**, 143-146.

From a study of their diets 137 pregnant women could be divided into 4 groups on the basis of their intake of milk and cheese, expressed in terms of liquid milk. Twenty-eight per cent. of the women consumed from 0 to 300 ml., 34 from 300 to 600 ml., 15 from 600 to 1000 ml., and only 23 per cent. more than 1000 ml., the quantity considered necessary to ensure a sufficient intake of Ca. A high percentage of pregnant women consumed small quantities of milk irrespective of their standard of education, their economic status, the number of their children, the total energy value of their diet or their consumption of maté, but those who did consume sufficient milk were characterised by their higher standard of education, their better economic status, and the higher total energy value of their diets.—M. B. Richards.

1080

MIRONE, L. Nutrient intake and blood findings of men on a diet devoid of meat. *Amer. J. Clin. Nutr.*, 1954, **2**, 246-251. [Dept. Nutrit., Univ. Georgia, Athens.] Spanish summary.

Six healthy members of a community consuming a diet low in animal protein were studied during a period of 6½ months when total animal protein intake was 10 g. and one of 5½ months when it was 23 g. A 3-day weight record of food intake during each period was kept for each subject. The average intake of energy, animal, vegetable and total protein, fat, carbohydrate, Ca, Fe, vitamins A and B₁, riboflavin, nicotinic acid, ascorbic acid and cholesterol was calculated and fasting blood samples were taken for analysis.

The diets had no apparent bad effect on the health of the 6 subjects and the addition of skimmed milk brought the nutritive values to within accepted standards. The values for cholesterol and cholesterol ester in blood serum were normal despite the low fat and cholesterol contents of the diets; the N.P.N. fractions of the blood were unaffected.—G. F. Garton.

1081

MINISTRY OF FOOD. Domestic food consumption and expenditure, 1952. Annual report of the

N.A. and R., January 1955

National Food Survey Committee. H.M.S.O., London, 1954, pp. 102. Price 4s. net.

The present report is the first for a full year since the Survey made the changes in methods referred to in Abst. 3556, Vol. 24. The report is in 4 main sections which contain 35 tables and it is supplemented by 5 appendixes with as many pages as the report itself and containing 40 more tables.

Some restriction of supplies of foods was associated with the critical state of Britain's balance of payments, but the year 1952 saw a resumption of the trend towards complete decontrol and, at the same time, a steady increase in expenditure on food.

The total value of consumption was 21s. 6d. per head per week; for the last quarter of 1951 it had been 19s. 6d. Expenditures on milk, meat, bacon and eggs increased. Consumption of meat in the last quarter was 11 per cent. greater than in the same period of 1951 and there was an associated downward tendency in fish consumption. The freeing of tea from rationing was not followed by any increase in its use. In terms of energy value and 8 nutrients there was no seasonal change throughout the year. Amounts of animal protein, fat and nicotinic acid were highest in the fourth quarter, findings which were attributable to the increases in amounts of meat and bacon, but the increase in iron accompanying these changes was more than counterbalanced by less use of peas and beans. When compared with the British Medical Association standards, intakes of energy and of the 8 nutrients were adequate.

To extend the study to social classes the same system as was used in earlier reports, of classifying households on the housewife's statement of income, was used. Although understatements were known to have been made the broad relationship between classes was not considered to be seriously in error. On the purchase of food Class A spent under $\frac{1}{4}$, Class B $\frac{1}{3}$, Class C nearly $\frac{2}{3}$, and the Old Age Pensioner (O.A.P.) group more than $\frac{1}{2}$ of their respective net incomes. Consumption and expenditure ranges were widest for fresh fruit. In energy and nutrient intakes Classes B and C were similar, Class A households higher and O.A.P. households lower than these, but it was only for iron in the O.A.P. group that deviation from the B.M.A. standard reached — 10 per cent.

The effects on household diets of family composition are considered more fully than in earlier reports. Households with 2 adults under 55 years of age were found suitable as a basis for the study of the effects of the presence of children. Average expenditure on an adult element was 57s. 3d. and for each additional child 8s. 6d. weekly. The addition of a child appeared not to affect the amount of fresh green vegetables used, and to

make little change to that of fresh fruit but when welfare and school milk were considered such an addition increased consumption of milk by nearly one-third. In households with 3 or more children intakes of protein and Ca were below requirements on the B.M.A. scale by 5 per cent. or more and in households with adolescents and children energy also was below assessed needs.

The 5 appendixes deal with technique and composition of the population, the effect of meals taken outside the home, the incidence of school milk and school meals, expenditure on subsidised foods, tables of consumption, expenditure and prices for 106 foods and the nutrient contributions of different foods. Among the findings are the following: the average uptakes were 78.5 per cent. for school milk and 44.1 per cent. for school meals; families with 1 child made less use of the services than did those with 2 or more children; there was reluctance on the part of adolescents to take school milk; in the nation's diet bread and other cereals were the main sources of energy, vegetable protein, Fe, vitamin B₁ and nicotinic acid; milk and cheese of animal protein, Ca and riboflavin; fats, vegetables and meat of vitamin A; potatoes and fruit of vitamin C and margarine and fats of vitamin D.—D. Harvey.

1082

MUKHERJEE, M. Estimation of national consumption of the United Kingdom from family budget studies. *Sankhyā, Indian J. Statistics*, 1954, 13, 412–416. [Nat. Income Unit, Minist. Finance, New Delhi.]

The official estimates of national consumer expenditure in the United Kingdom based on national income statistics are compared with sample estimates obtained in Britain from 8905 industrial working class families alone or combined with 1491 families of agricultural workers. The data were collected in 1937 and 1938. Food, clothing, rent, rates and water charges, fuel and light form 4 item groups and a fifth refers to 8 other heads of expenditure, tobacco, books and newspapers, entertainment, travel, communication service, drink, household goods and the rest. Estimates for the industrial workers alone are nearer to the official estimates, as was to be expected since agricultural workers were the poorer.

Sample estimates for clothing and rent are close to the official estimate; those for food and fuel and light are considerably higher. For food, sample estimates were uniformly higher than the official ones. The differences may be explained on rational grounds and it is concluded that a properly designed family budget inquiry need not be very large in order to obtain a reasonably accurate measure of national consumption.

D. Harvey.

MULDER, T. Nationaal budgetonderzoek 1951. [National Budget Investigation, 1951.] *Voeding*, 1954, 15, 352-354.

This is the second publication from the Centraal Bureau voor de Statistiek, Utrecht, on the 1951 budget survey and deals with expenditure, including expenditure on 69 groups of foods in 16 classes. For the first report see Ornstein, *Abst.* 2291, Vol. 24.—I. Leitch.

1084

GASNIER, A., LORANGER, M. B. and BROUHA, L. L'alimentation des ouvriers canadiens-français d'une usine de l'Aluminium Company of Canada. [Nutrition of the French Canadian workers at a factory of the Aluminium Company of Canada.] *Rev. canad. Biol.*, 1953, 12, 355-395. [Dept. Nutrit. Indust. Physiol., Inst. Hyg., Fac. Méd., Laval Univ.] English summary.

A survey was made in 1946 of the boxes of food brought to eat at work by French Canadian workers at the Shawinigan Falls factory of the Aluminium Company, which makes cables. There are 3 eight-hour shifts, beginning at midnight on Sunday and ending at midnight on Saturday. What was brought and what was left were weighed for 4 or 5 days in 3 successive weeks between February and July. The number of boxes of food examined was 2668, brought by 110 men. The very varied foods were classified by the method of Berryman and Chatfield (*Abst.* 41, Vol. 13) into 17 groups slightly modified.

No difference could be found in the food brought to be eaten on the 3 shifts. The results for the 3 shifts could, therefore, be considered together. Dietary habits did not vary greatly according to season except as dictated by what was available. The foods preferred were bread, butter, pastries, meat and fruit, with tea to drink; tomatoes were particularly liked. Sandwiches predominated; there was not time for heating up food. From the results, a mean daily menu was constructed, and its nutritive value was calculated for winter and summer from the tables of Berryman and Chatfield (*loc. cit.*). The number of Calories provided by it was about 1300. If the daily requirement is put at 3000, the corresponding contribution of other nutrients, on the basis of their representing 1300/3000ths of the total daily intake, was worked out, and the result was compared with the requirements laid down by the U.S. National Research Council (*Abst.* 3507, Vol. 15). By these criteria, the amounts of animal protein, Ca, vitamin C, riboflavin, and nicotinic acid were too small, and more milk, dairy products, citrus fruits, meat, fish, and raw vegetables such as celery and lettuce should be eaten. The intake varied very greatly between

individuals, and for many of them was much less favourable than is represented by the mean. Examples are given for 2 workers of whom the intake of one was satisfactory in almost every particular, and of the other deficient in everything except energy and fat.—E. M. Hume.

1085

HAMES, P. J. and ROBERTSON, E. C. Nutritive value of low-income families' diets. Suggestions for improvements. *J. Amer. Dietetic Assoc.*, 1954, 30, 766-773. [Dept. Paediat., Univ. Toronto.]

During a period of 2 years 1030 family food records were obtained from 373 families in Toronto. The method of study was the one-week record with inventories at beginning and end. Intakes of Ca, vitamin B₁, riboflavin and ascorbic acid were computed and compared with recommended allowances of the U.S. National Research Council. Approximately 25 per cent. of families met the allowances in Ca and vitamin B₁, 60 per cent. in riboflavin and 40 per cent. in ascorbic acid. Variations in intakes from survey to survey were analysed in the 136 families studied 4 or 5 times. The results indicated that one survey of one week does not usually give a reliable picture of a family's diet. The greatest variation was in ascorbic acid intake. Variations in intakes of other nutrients were attributable to food price changes, but this was not so for ascorbic acid.

Recommendations for diet improvement included greater use of skimmed milk, whole grain or refined cereals, citrus fruits and tomatoes and less use of sweet baked goods, canned soups, potato chips and meat.—F. C. Aitken.

1086

MUSE, M. and JOHNSTON, R. Diets of Vermont farm families. *Vermont Agric. Exp. Stat. Bull.* No. 573, September 1953, pp. 32. [Burlington, Vt.]

Homes in the best farming lands of Vermont were visited between May and August 1948 and data were obtained by the interview method for 365 households. The basis of assessment was a "master food plan at low cost" which gave weekly quantities of food in each of 11 groups for each member of the family. It was found that by the standards selected, 68 families had poor, 228 medium and 69 good diets. The findings showed a slight improvement over those in 1943 by Muse (*Vermont Agric. Exp. Stat. Bull.* No. 530, 1946).

By a series of calculations which are described the diet of the modal class, which contained 56 of the families with medium diets, was arrived at and its nutrients are compared with those for a family of the same average composition calculated from recommended allowances. Of these 56 families 45

N.A. and R., January 1955

did not use the prescribed amount of green vegetables, 30 of citrus fruits and tomatoes, 37 of dried legumes and nuts and 39 of bread, flour and cereals but the amounts of energy and of 8 nutrients in the representative diet were in excess of recommended allowances by between 36 and 85 per cent. The greatest excess was in protein which suggested that the feeding of these families was more expensive than it need have been.

The households with the best meals were generally favoured since the comparison was with a low-cost diet.

Of the 68 with poor diets the modal group of 20 families had, in general, less than recommended of citrus fruit, green vegetables, eggs, dried legumes and cereals and baked foods. The system of comparison showed that amounts of protein and iron were in excess of recommendations but those of energy, calcium, vitamins A and B₁, riboflavin, nicotinic and ascorbic acids were low or only in slight excess.

The contributions made by milk and enriched foods to these results are indicated. Possible reasons why some families are better fed than others are discussed in relation to their economic status, their tenure of land whether as owner, renter, manager or labourer and to the general managerial attitude of the homemaker.

D. Harvey.

1087

LAL, S. B. Changes in dietary habits and physique of aborigines in Santhal Parganas, a district of Bihar. *Indian J. Med. Res.*, 1954, 42, 167-179. [Pub. Health Labs., Patna-4.]

This report is based on a survey, repeated in 1951-52, of Santhals, Sauripaharis and Malpaharis originally examined in 1938-39 by Mitra (see Abst. 2862, Vol. 10). Seven-hundred and sixteen adults over 18 years, 414 men and 302 women, were weighed and measured of whom 477, 132 and 107 belonged, respectively, to the communities in the above order. The earlier finding that Santhals were taller than the others was not confirmed.

At the time agriculture was not prosperous and prices of foods and of other necessities were from 1½ to 3 times those prevailing during the earlier investigation. No change had occurred in feeding habits.

A diet survey was made of 200 families with 946 persons. Although family incomes had risen increases in consumption were recorded only for cereals and pulses; in general there was a decrease in the use of green vegetables and little change for milk, fruits and nuts, and fats and oils. Intakes of all but cereals were below the recommendations by the Indian Nutrition Advisory Committee. The average daily intakes per consumption unit for nutrients were, protein 67.6 g. (1.8 per cent.

of animal origin), fat 12.8 g., carbohydrate 499 g., calcium 0.24 g., vitamin A 442 I.U., vitamin B₁ 680 I.U. and vitamin C 12.6 mg. 92 per cent. of energy was from cereals.

Weight and height measurements and clinical examinations were made of 2204 children between 3 and 14 years of age. Boys were taller after 7 years and girls after 9 years than were children of the same sex in 1939. Clinically they were in 4 groups, 276 good, 1585 fair, 224 poor and 119 very poor. The earlier survey recognised only 3 groups, good, fair or poor, and the examinations were by medical officers other than those making this later survey. Nevertheless the evidence was that the children in the present were in a better nutritional state than those in the earlier survey. Defects are tabulated under 24 headings for eyes, mouth, hair and skin; the incidence of these signs was generally lower among Santhal than among Pahari children.—D. Harvey.

1088

ADOLPH, W. H. Nutrition in the Near East. *J. Amer. Dietetic Assoc.*, 1954, 30, 753-756. [Dept. Nutrit., American Univ., Beirut, Lebanon.]

This account is based mainly on observations in Lebanon and Syria. Urban diets in general conform to the United States pattern, but rural diets as taken by a large part of the population are widely different. In terms of percentage of total calories from different foods the rural diet consists of cereals and legumes 73, vegetables and fruit 12, sugar 3, fats and oils 7, meat 2 and milk 3. The staple cereal is whole wheat, which is eaten as bread or parboiled and dried. Milk is taken as "leban", the equivalent of yoghurt. Surveys of the rural diet in Lebanon suggest that the diet is low in protein, Ca and possibly riboflavin. There are few data on nutritional status, but observations indicate that malnutrition is widespread. Educational programmes should stress the value of green vegetables and of protective foods generally. Protein intake could be improved by increasing the supply of suitable legumes.—F. C. Aitken.

1089

HOLMES, S. A qualitative study on family meals in Western Samoa with special reference to child nutrition. *Brit. J. Nutrition*, 1954, 8, 223-239. [S. Pacific Health Serv., Headquarters Office, Suva, Fiji.]

A survey of eating habits was made on the Samoan islands of Manono and Upolu in December 1950 and January 1951. Methods were devised for collecting the required information and many surprise visits were paid to individual households, particularly at times when food was being prepared and eaten. Descriptions are given of the social background of the people and of the traditional

methods of preparing and cooking food. Most foods were homegrown but some, e.g. sugar, tinned meat and rice, were imported. Bread-fruit, taro and green banana were the principal sources of energy; no cow's milk is produced on the islands and fish, shellfish and eggs, with small amounts of pork and chicken, supplied most of the animal protein. The diet of the weaning child was the least satisfactory. Breast feeding was often continued for as long as 20 months, after which the diet tended to be deficient in protein; nevertheless, kwashiorkor was not seen. It is believed that a suitable weaning diet, details of which are given, could be prepared were sufficient trouble taken and proper use made of the available foods.—G. F. Garton.

1090

HUENEMANN, R. L. **Nutrition and care of young children in Peru. 1. Purpose, methods and procedures of study.**

HUENEMANN, R. L. and COLLAZON C., C. 2. **San Nicholas, a cotton hacienda, and Carquin, a fishing village, in the coastal plain.** *J. Amer. Dietetic Assoc.*, 1954, **30**, 554-558; 559-569. [Sch. Pub. Health, Univ. California, Berkeley.]

These studies were linked with those described in *Abst.* 2269, Vol. 24.

1. The organisation and aims of the investigations which were made in 5 communities in Peru are described. In the coastal region a cotton plantation in San Nicolás and Carquin, a fishing village, were chosen and in the Southern and Northern Sierras, respectively, a farming community at Chacana and the Vicos plantation were selected. Yurimaguas is a jungle town. Data were collected by field workers who visited the homes once or twice daily for a week. The findings were compared with the U.S. National Research Council recommendations. The precautions required for success in work of this kind are summarised.

2. This report deals with 38 children, 17 boys and 21 girls, of whom 16 were in San Nicolás and 22 in Carquin. Their age distributions were 12 under 1 year, 16 between 1 and 2 and 10 between 2 and 3 years. Findings are tabulated for the nutrients lacking in the family diet at the time of the survey, those thought likely to have been deficient during the pregnancy, the child's past and present diet, its weight, height and dentition and clinical signs possibly related to nutritional deficiencies. There is also an assessment of its general physical condition.

Weaned children were commonly short of calcium but about half of them were not getting the recommended amounts of vitamin A, riboflavin, protein and iron. Clinical signs were seen in 23 of the children.—D. Harvey.

RODRIGUEZ MIRANDA, J. V., DE BLANCHET, R. V. and COLOMBO, M. J. **Trabajo de parto y alimentación. [Parturition and diet.]** *Rev. Asoc. argent. Dietología*, 1953, **11**, 94-104.

The diet of 69 women was directed during the last trimester of pregnancy. Women weighing less than 70 kg. at the sixth month were given directions for a diet supplying 2200 Cal. and 77 g. protein daily, those weighing more than 70 kg., 2700 Cal., 115 g. protein and a restricted amount of salt. The diets are fully described.

All gave birth to healthy infants; one woman required forceps for delivery of the first of twins, and one had caesarean section for occlusive placenta praevia and pelvic presentation. It is considered that the controlled regimens were conducive to brief and normal labour, a normal puerperium, healthy infants and good lactation. The dietary requirement in late pregnancy is estimated at 2500 Cal. daily.—D. Duncan.

1096

ESTOPAN, M. E. **Alimentación de la embarazada normal y gestosica. [Diet in normal and abnormal pregnancy.]** *Rev. Asoc. argent. Dietología*, 1953, **11**, 123-138.

In this lecture the author considers the dietary requirements of a normal man and woman, works out the energy, protein, mineral and vitamin requirements of a woman in the 4th and 7th months of a normal pregnancy, and gives a table of the quantities of different foods necessary at 7

months for a pregnant woman performing domestic duties. The dietetic treatment of abnormal pregnancy, described in an earlier work, has been applied with success to patients in the Maternity Hospital at Cordoba, in simple oedema, glomerulonephritis of pregnancy, eclampsia and chronic glomerulonephritis exacerbated by pregnancy. A case history is given for each type of disorder. Four dietary regimens are used successively, with the general aim of giving sufficient energy and tending to excess of protein with a high proportion of animal origin, to low Cl and to a high K : Na ratio.—M. B. Richards.

MIRONE, L. and HARVEY, L. G. A new menu pattern is tested. *J. Amer. Dietetic Assoc.*, 1954, **30**, 757-761. [Dept. Nutrit., Univ. Georgia, Athens.]

Under the National School Lunch Programme in the United States of America lunches must meet minimum nutritional requirements. Type A lunch was based on the needs of a child of 10 to 12 years of age, but a number of surveys (see Absts. 2187, Vol. 16, 4067, Vol. 20 and 5264, Vol. 21) have indicated that school lunches may be inadequate. The menu pattern was re-examined (*Guide for Planning Menus to Meet the Tentative School Lunch Food Requirements and Guide for Quantities of Food to Meet Tentative School Lunch Requirements*, U.S. Dept. Agric. Bureau of Human Nutrition, 1952). The new pattern has been tested and is considered to be superior to the earlier plan.—F. C. Aitken.

1099

VIGLIANI, E. C. Dieta e bevande per i lavoratori delle industrie tessili durante la stagione calda. [Diet and beverages for workers in the textile industry during the hot season.] *Med. del Lavoro*, 1954, **45**, 277-285. [Clin. Lavoro "Luigi Devoto", Univ. Milan.]

In textile factories in Italy in hot weather, the conditions are such that workers may lose as much as 6 litres of water a day as sweat. The workers' diet is not rich in NaCl, and it is recommended that there should be available for them a powder containing NaCl like that recommended by Stewart (*Brit. J. Indust. Med.*, 1945, **2**, 102) and easily made into an effervescent, palatable drink.

Vol. 25, No. 1

Work is usually in two 8-hr. shifts, from 6 a.m. to 2 p.m. and from 2 p.m. to 10 p.m., with a half-hour break for meals, which is considered insufficient for the kind of meal considered necessary in view of the distribution of the shift times over the day.—E. M. Hume.

PILLE, G. Le problème de l'alimentation Outre-Mer (Afrique Noire Française). Aspects biologiques et scientifiques. [The problem of nutrition in France Overseas (French black Africa): biological and scientific aspects.] *Méd. trop.*, 1954, **14**, 1-34. [Corps de Santé Colonial.]

The paper makes a general survey. It reviews quantitative and qualitative needs for food in the tropics. The diet is sketched of the different communities, nomadic herdsmen, fishermen, small cultivators, urban working class and small salaried workers; examples of their diets are given. Insufficiency in quantity and quality, particularly of protein, is severe. The problem of increasing industrialisation and urbanisation is recognised, and recommendations are made, based on cultivation of groundnuts and rice and importation of more rice, in spite of the dangers of increasing the cultivation of rice in country infested with bilharzia, and of substituting rice for millet. To provide more animal protein, dried and defatted fishmeal is suggested, especially for regions where the tsetse fly makes the keeping of cattle impossible. An ample supply of crude sea salt, furnishing iodine as well as NaCl would, it is believed, transform the men and animals far from the sea in French Africa. Exclusion of alcoholic drinks is desirable.—E. M. Hume.

RYER, R. (III), GROSSMAN, M. I., FRIEDEMANN, T. E., BEST, W. R., CONSOLAZIO, C. F., KUHL, W. J., INSULL, W. (Jr.) and HATCH, F. T. The effect of vitamin supplementation on soldiers residing in a cold environment. 2. Psychological, biochemical and other measurements. *J. Clin. Nutr.*, 1954, 2, 179–194. [U.S. Army Med. Nutr. Lab., Denver, Colo.] Spanish summary.

The organisation of the study was fully described in the first part (Abst. 5115, Vol. 24).

The subjects were given diets providing daily intakes ranging from 4138 to 2056 Cal. The ascorbic acid content of the basal diet ranged from 36.0 to 43.3 mg. daily. Half the subjects received 4 times a day a capsule containing B vitamins and 300 mg. ascorbic acid. The other half received a capsule containing 6 mg. ascorbic acid only.

None of the 6 psychological tests revealed a significant difference between the groups. There was no statistically significant difference between the groups in excretion of N, creatinine or 17-ketosteroids in the urine, in blood sugar or in Hb. Ascorbic acid in blood and urine was higher in those having the high vitamin supplement. In both groups exposure to cold caused a statistically significant increase in excretion of oxidised ascorbic acid. There was a fall in eosinophil count during forced marches, and a loss of bodyweight during the experiment, both significantly greater in those having the high supplement. There was no significant difference in morbidity records. Neither group showed any sign attributable to vitamin deficiency or underfeeding.—F. C. Aitken.

TUTTLE, W. W., DAUM, K., LARSEN, R., SALZANO, J. and ROLOFF, L. Effect on school boys of omitting breakfast. Physiologic responses, attitudes, and scholastic attainments. *J. Amer. Dietetic Assoc.*, 1954, 30, 674–677. [Dept. Physiol., Coll. Med., State Univ. Iowa, Iowa City.]

Twenty-five boys aged 12 to 14 years were studied. The physiological responses were measured as in previous studies of adults (Absts. 2112, Vol. 20; 771, Vol. 22). Neuromuscular tremor, choice reaction time, grip strength and grip strength endurance were unaffected by omission of breakfast. Maximum work rate and output in the late morning were significantly less when breakfast was omitted than when breakfast was eaten. Reports of teachers on attitudes and attainments of boys were more favourable during the periods when breakfast was eaten.

CHANDRASEKHAR, S. Population growth, socio-economic development and living standards. *Internat. Labour Rev.*, 1954, 69, 527-546. [London Sch. Econ.]

An Indian economist examines the growth of population in relation to production. He would replace political and economic domination in

colonial territories by compulsory control of population and regards universal birth control as the essential way to raise or preserve standards of living. It will be helped by planned migration and, within limits, by industrial development. Yields per acre must be improved by provision of fertilisers where there are none, improved techniques and reformed land tenure. The aim should be "one baby in the place of three or more" and "two or more ears of corn where one or none grew before". (See also Absts. 1044 and 3593, Vol. 24.)—I. Leitch.

1124

SCHULZ, T. A 'human needs'; diet: spring 1954. *Bull. Inst. Statistics Oxford*, 1954, 16, 130-136. This, the last survey before the end of rationing, was made in Easter week, but the holiday did not affect the prices of the foods concerned, though certain other foods did rise in price. The cost of

the "human needs" diet was 63s. 7d., about 1 per cent. higher than in autumn 1953 (Abst. 5114, Vol. 24) if a special allowance of 2s. 3d. then made for the housewife's inexperience of a partly de-controlled market is disregarded. The "simple" diet (loc. cit.) cost 56s. 8½d. The intakes of nutrients more than met the recommendations of the British Medical Association except for Ca (0.7 g. daily instead of 0.8 g.); there was no change from the previous autumn except for the considerable seasonal fall in vitamin C.—W. M. Deans.

KERN, A. Utilisation du lait de brebis en Israël. [Use of ewe's milk in Israel.] *Lait*, 1954, 34, 408-422.

Present-day milk products in Israel differ considerably from the original Bedouin ones, of which descriptions are quoted, and most of the cheeses are imitations of European types developed by and for Jewish immigrants.

"Brinsen" cheese is the one most closely resembling the indigenous Arab products. At first it was very variable in composition but later a uniform cheese was produced, by a method described, from pasteurised ewe's milk, two-thirds whole and one-third skimmed, with fat 36.5, water 50 and salt 4.5 per cent.; yield about 25 kg. from 100 litres. At present, however, owing to the shortage of liquid milk, "Brinsen" is produced all the year round from a mixture of 90 per cent. re-constituted dried milk (imported) and 10 per cent. fresh milk and vegetable fat.

A cheese of Roquefort type is also made, and ewe's milk is mingled with cow's milk in the manufacture of other European types of cheese. Considerable amounts of kashkaval cheese are made by Balkan immigrants.

Last year's production of cheese of all sorts in Israel in metric tons was: 4730 of soft white cheese, mostly from dried skimmed milk; 1500 of white "cream" cheese, from dried skimmed milk and vegetable fat; 910 of processed cheese, from imported cheese and dried milk, and 1528 of "Brinsen", "Safed" (similar to "Brinsen"), Roquefort, Edam and the like. The yearly consumption is high, 7 kg. per head.

The Jewish dairy industry does not deal in

liquid ewe's milk or ewe's milk butter, owing mainly to difficulties arising from the high viscosity and frequent bacterial contamination of ewe's milk or admixture with goat's milk.

Yoghourt, whether made from ewe's milk or cow's milk, has not been a commercial success in Israel. "Lebben", an acid milk imitated from the Arab product, but made from cow's milk, and now from dried skimmed milk and vegetable fat, was more popular, but is being rapidly superseded by "lebberia", originally a mixture of leben and soft white cheese, now a product with 15 per cent. solids of which 11 are dried skimmed milk and 4 vegetable fat; 20 million litres of this were produced last year.

As immigration slows down and home milk production rises, problems of utilisation of ewe's milk will return to prominence. Cow's milk is paid for on a basis of fat content, 3.5 per cent. being regarded as standard; for ewe's milk, the method of payment has fluctuated, sometimes to the advantage and sometimes to the disadvantage of producers. The difficulty will probably be got over by having separate creameries for ewe's milk, or rigorously separating the milks in the present creameries. See Abst. 261, Vol. 25.

FOX, F. W. The agricultural foundation of nutrition. 6. Wheat. 7. Pastoral production: meat. *S. African Med. J.*, 1954, 28, 542-546; 649-653. [*S. African Inst. Med. Res.*]

For earlier studies see Absts. 3594 and 5556, Vol. 24.

6. Production of wheat as measured by sales to the Wheat Industry Control Board was 7109 thousand bags in the year 1951-52; for the period 1938 to 1947 average annual production was 3869 thousand bags. The proportion of the crop originating in Orange Free State has risen steadily and is now 45 per cent. of the total. Yields are low, about 6 bags or 1200 lb. per morgen (2.116 acres). Consumption has risen steadily since 1920 and for 1956-57 has been estimated as likely to be 10½ million bags. Of the 2 principal producing areas, Western Province and Orange Free State, the first is unlikely to be able to increase output because of climatic conditions and disease but in the second the outlook is more promising. It is, nevertheless, unlikely that South Africa will ever be able to meet her needs from local sources; at present about 40 per cent. of supplies are imported. The question is raised whether it is advisable to continue to subsidise wheat consumers, at a rate which at present is £7 million annually, in preference to promoting, by similar subsidies, the greater production and consumption of maize.

7. Data are presented to show the area of land

N.A. and R., January 1955

available for grazing and the livestock population and numbers slaughtered over about 40 years. From the data of Alvord (*Thesis*, in the press) the natural veld is concluded to be the mainstay of the South African livestock industry, supplying 90 per cent. of digestible protein and 86 per cent. of total digestible nutrients. Total meat production has, from abattoir records, risen steadily since 1920, largely because of the increase in beef production.

Problems in connection with restoration of the veld by improving management or by fertilising and with the reduction of losses caused either by death or by underfeeding in the dry months are briefly considered.—D. Harvey.

GENERAL STUDIES

1130

SEN, M. and MATHEN, K. K. Inquiry into the vital losses of pregnancy and infancy in a rural population. *Indian J. Med. Res.*, 1954, **42**, 267-278. [Dept. Maternity, All-India Inst. Hyg. Pub. Health, Calcutta.]

The inquiry was made in the period April 1949 to March 1950 in 68 villages in the Singur area near Calcutta, which has a population of about 63,000. The sample studied was not completely representative and the findings are based largely on reports by health visitors from their observations during routine antenatal visits.

Abortion and stillbirth rates were about 50 and 45 per 1000 pregnancies and total births, respectively. Among mothers recorded as free from disease throughout pregnancy the still- and premature-birth rates were considerably lower than among those in whom signs of disease had been noted. Dysentery and diarrhoea were associated with high rates; deficiency diseases in the mothers did not noticeably affect these rates.

Causes of deaths of infants were diagnosed from histories provided by parents or relatives, since very few children had been attended by doctors during their illnesses. Of 418 deaths recorded for infants under 1 year, prematurity, in 152 cases, was the commonest cause; malnutrition was ascribed in only 10 cases.—D. Harvey.

BROWNE, E. M. A survey in Singapore of low income level housing in relation to health of infants. *Med. J. Malaya*, 1954, **8**, 222-239. [Dept. Social Med. Pub. Health, Univ. Malaya.]

A detailed analysis is given, with illustrations, of the housing conditions of 114 Southern Indian and 103 Chinese infants who had been born in a maternity hospital in Singapore. The basis of assessment of these conditions is described and they were grouped as satisfactory, fair or bad. The weights of the children were taken at monthly intervals, clinical examinations were made at birth and shortly before first birthdays, and records of illnesses were kept during the year.

The differences in housing conditions of the 3 groups were not related to any difference in percentage increase of weight between the groups. The incidence of infection was high among the infants, occurring in about 20 per cent. of the Indians any time after age 2 months and in about 40 per cent. of the Chinese in the second half of the year.—D. Harvey.

BRAS, G., JELLIFFE, D. B. and STUART, K. L. Histological observations on hepatic disease in Jamaican infants and children. *Doc. Med. geogr. trop.*, 1954, 6, 43-60. [Dept. Pathol. Med., Univ. Coll. W. Indies, Jamaica.]

On 93 children of predominantly African descent, 148 liver biopsies and 12 autopsies were made. Diet from the age of weaning at from 7 to 9 months is chiefly carbohydrate with many bush teas. Deficiency of protein, Fe and elements of the vitamin B complex is common.

Of the 93 children, 39 were classified as suffering from kwashiorkor-marasmus, within which group 3 subgroups were recognised. Twelve were diagnosed as having veno-occlusive disease affecting the hepatic veins and, in the chronic form, producing cirrhosis of the liver. The children were less undernourished than those with kwashiorkor, and the disease was thought not to be wholly nutritional in origin. Toxic substances in bush teas are possibly implicated. Eight patients had cirrhosis of the liver which was advanced, but in some a relation to the liver conditions in the 2 foregoing groups could be traced. Thirty-four children were examined as a control group. Half of them were thin and undernourished but not ill, and half had other non-hepatic diseases such as sickle cell anaemia. The liver biopsies showed no unexpected pathological change.—E. M. Hume.

1135

GRÖRGY, P. Nutrition in liver disease. *Nat. Vitamin Found., Inc., N.Y., Nutrit. Symposium* Ser. No. 6, 1953, 139-147 (with discussion

147-149). [Hosp. Univ. Pennsylvania, Philadelphia.]

Dietary nutrients which prevent liver cirrhosis and necrosis in rats are listed. Those which prevent cirrhosis have in common that they are sources of lipotropic substances or possess choline-sparing effect. Dietary cirrhosis would appear to be in the main a deficiency disease. The dietary substances which prevent necrosis are as widely different as sulphur amino-acids and vitamin B₁₂, and it is suggested that this condition is not the result of a pure deficiency. The necrosis-delaying effect of antibiotics is cited in favour of a toxic etiology. Observations are presented which suggest that the antibiotics exert an antimicrobial effect on the intestinal flora rather than a direct metabolic effect.

The possible application of the results of experimental work to the prophylaxis and treatment of liver disorders in man is discussed.—F. C. Aitken.

HULSHOFF, A. A. Medical examination of repatriated Dutch nationals from Indonesia, 1946-1951. *Doc. Med. geogr. trop.*, 1954, 6, 131-141 (with discussion 141-143). [Harbour Hosp., Rotterdam.]

In the period 1946-51, 1663 persons returned from Indonesia were examined in the out-patient department of the Harbour Hospital. They included former internees, prisoners of war and other ex-service men. Nutritional disease was mentioned as part of their case history by 1530, including oedema 517, beriberi 236, pellagra 235, and oral distress 107, but only 129 still had signs. The majority were already in quite good condition on arrival in Holland. Hypotension was present in 253. The liver was enlarged in 313, often through amoebic dysentery or malaria, but malnutrition may have played some part though not a large one; cirrhosis was not found. Fatigue was complained of more frequently after deficiency disease than after the other non-nutritional diseases.

1139

ROBINSON, E. Medical aspects of the Domasi development area, Nyasaland. *J. Trop. Med. Hyg.*, 1954, 57, 131-137.

The Domasi development area covers about 100 sq. miles of which roughly one-half is inhabited by 14,000 people. A medical survey was made in which 22 villages, about one-fifth of the total, were visited in each of which about the same proportion of the population was seen. Data are given for the incidence of schistosomiasis, malaria, liver and spleen enlargement, leg ulcers and blindness and for Hb and Kahn reaction and sensitivity to tuberculin.

The one clinical sign looked for which had direct nutritional significance was skin manifestation of pellagra. Positive evidence was seen in 8 of 328 subjects under 5 years, 21 of 229 between 5 and 18 and 42 of 581 over 18 years of age. Females appeared to suffer more than males and the impression was gained that they received less of the protein and protective foods.—D. Harvey.

KEYS, A. Obesity measurement and the composition of the body. *Nat. Vitamin Found., Inc., N.Y., Nutrit. Symposium Ser. No. 6*, 1953, 13-35. [Lab. Physiol. Hyg., Univ. Minnesota, Minneapolis.]

The limitations of height-weight-age tables for the evaluation of relative obesity are discussed.

Vol. 25, No. 1

Three methods of estimating body fat, by measurement of body sp. gr., of body water or of subcutaneous fat, are appraised.

Summarised results of studies of body fat made at Minnesota show that, in clinically healthy men of normal weight for height and age, there is a large progressive increase of body fat with age. In prolonged undernutrition there is a progressive loss of both fat and active tissue, with little or no change in extracellular fluid. In experimental obesity weight gain is roughly 80 per cent. pure fat and 20 per cent. water, with little or no change in active tissue. Data obtained indicate that most of the age and sex differences in B.M.R. are reflections of differences in the amounts of active tissue.

HUNT, E. E. (Jr.), PECKOS, P. S. and FRY, P. C. Factors in human obesity. *Nat. Vitamin Found., Inc., N.Y., Nutrit. Symposium Ser. No. 6*, 1953, 73-87 (with discussion 87-89). [Forsyth Dent. Infirmary Child., Boston, Mass.]

Of 79 healthy white American children 35 had fat pads in at least 2 of the 3 regions, dorsal, abdominal and trochanteric. The others served as non-obese controls. The groups did not differ significantly in degree of resemblance to their mothers' body build, ethnic ancestry or family disorganisation. The fat pad group were relatively advanced in dental emergence and ossification of wrists and hands. A questionnaire study of the diets of these and other groups of children classified morphologically indicated no significant dependence of energy intake on body build in boys. Fat girls tended to eat less than other girls. There was no significant difference in protein intake between fat and control children.

A further study of children's body build in relation to that of their mothers was made on Micronesians of Yap and from published data on white Americans. There was some tendency for sons, but not daughters, to resemble mothers in body build, but the results were not statistically significant.

In the discussion the validity of the findings of questionnaire diet studies was doubted.

WAHL, K. Appendicitis und Ernährung. [Appendicitis and nutrition.] *Münch. med. Wochenschr.*, 1954, **96**, 489-490. [Engels-Stift, (22c) Nümbrecht, Cologne.]

During the years from 1944 to 1947 no case of acute appendicitis came for operation in a Russian prison camp of from 8000 to 10,000 men having a very meagre diet of bread, cabbage soup and porridge with almost no animal protein or fat. After 1947 the food was improved and 3 patients were operated on in 1948 and 3 in 1949. It is suggested that improvement in the diet affected peristalsis and the gut flora, and favoured the occurrence of irritation and inflammation in the appendix.—A. M. Copping.

1147

LOWENSTEIN, F. W. Some epidemiologic aspects of blood pressure and its relationship to diet and constitution with particular consideration of the Chinese: a review of the pertinent literature of the past 40 years. *Amer. Heart J.*, 1954, **47**, 874-886. [Flushing, N.Y.]

The scanty data on blood pressure in the Chinese are discussed and compared with U.S. data. It is concluded that in spite of differences in technique, the lower values found in Chinese people represent a real difference, not wholly accounted for by differences in body build or endocrine constitution, and it is suggested that differences in diet may play a part directly, as well as indirectly through their effect on bodyweight. There are 62 references, of which about 10 relate to China.

General

1149

PICK, W. Malnutrition of the newborn secondary to placental abnormalities. *New Engl. J. Med.*, 1954, **250**, 905-907. [Burbank Hosp., Fitchburg, Mass.]

Three infants, 2 born at term and one born 2 weeks after term, are described. Their weights at

birth were 1.6, 1.8 and 2.2 kg. and their crown-heel lengths 48.3, 48.3 and 53.3 cm.; they all looked emaciated.

The infants lost little weight after birth and then gained very rapidly, so that they were "indistinguishable from full term infants at the age of four to six months". The low birthweight of the babies is attributed to malnutrition due to abnormal placentae, which were all small and appeared degenerate. Two were examined microscopically and showed proliferate endarteritis of the umbilical arteries and areas of hyalinisation.

JELLIFFE, D. B., BRAS, G. and STUART, K. I. Kwashiorkor and marasmus in Jamaican infants. *West Indian Med. J.*, 1954, **3**, 43-55.

The feeding of infants in Jamaica after weaning is briefly described. Thirty-one malnourished children aged from 6 to 31 months were studied between September 1952 and July 1953; clinical and haematological examinations and serological tests for syphilis and Mantoux tuberculin tests were made, liver function was measured by 6 different tests and serum proteins were estimated. On a clinical basis 18 were classified as suffering from kwashiorkor, 9 from marasmic kwashiorkor and 4 from marasmus, but the classification is admittedly rough and without clear-cut boundaries.

The physical signs are described with illustrations. The biochemical data showed no difference between the groups; when combined they showed low averages, 5.1 g. for total protein and 2.7 g. for albumin, and a normal level, 2.4 g., for globulin per 100 ml. serum and an albumin:globulin ratio of 1.1:1. Abnormalities in these were not as great as have been reported from elsewhere. Hb was also low. From biopsy material there was evidence that liver fat was greater in the kwashiorkor group than in the 2 other groups and that it was least in amount in the marasmus group.

Treatment was with increasing amounts of

N.A. and R., January 1955

skimmed milk in the diet, with attention to intercurrent infections. Those with kwashiorkor, in contrast to African patients, responded readily to the treatment; those with marasmic kwashiorkor were the most difficult to treat.—D. Harvey.

1153

THOMPSON, M. D. Protein shortage in African children: some causes and effects. *East African Med. J.*, 1954, **31**, 127-142.

The clinical data were from 164 children aged from 1 to 6 years and admitted to Mulago Hospital, Kampala with established kwashiorkor. In those patients where examination was made, values for serum protein and for pancreatic enzymes obtained by intubation were low. Routine treatment in hospital was with high-protein diet. Examples are given of failure when high intake of protein could not be secured. From questioning, it appeared probable that very few of the patients had been offered as much as 20 g. protein daily, and that 80 or 90 per cent. of the children without kwashiorkor got no more than that. Other circumstances which tend to reduce protein intake and to increase protein requirement are discussed. Almost all the kwashiorkor patients had a history of some infection.—E. M. Hume.

1154

OOMEN, H. A. P. C. Het uitwendig patroon van wanvoeding bij kleuters te Djakarta. [The external pattern of malnutrition in children in Djakarta.] *Nederlandsche Tijdschr. Geneesk.*, 1954, **98**, 1686-1696. [Inst. Volksvoeding, Djakarta.] English summary.

The diet, the economic background and the selection and examination of the children, who were from 1 to 6 years of age, have already been described (Abst. 3608, Vol. 24). The clinical pattern is referable to underfeeding, lack of protein and deficiency of vitamin A. The children are short for their age and light for their height. The skin is dry and scaly, sometimes with patchy exfoliation, giving "crazy pavement dermatosis". This dermatosis affects certain areas, e.g., the napkin area, which differentiates it from pellagra. It is characteristic of kwashiorkor and suggests fatty degeneration of the liver. The normal child has black hair and a coffee-coloured skin; the sick child is depigmented. Other abnormalities are: rhagades, superficial ulcers, angular stomatitis, overgrown lanugo and folliculosis. There is considerable atrophy of muscle and there may be oedema of any grade up to ascites and anasarca. At this stage xerophthalmia and keratomalacia are found, and, of less diagnostic value, cheilosis, atrophic glossitis and gingivitis. The liver is enlarged. The children are apathetic or defensive. Mortality is 80 per cent. in those not treated.

A malnutrition index assesses the state of the

Vol. 25, No. 1

individual child. The age distribution of 124 sick children aged 1 to 6 years is shown in a diagram. Those with xerophthalmia, two-thirds of the whole number, are on the average older than those without. The reason is not obvious.

Liver biopsy of 42 patients confirmed that the enlargement is referable chiefly to fatty degeneration. There is no relation between enlargement of the liver and either oedema or xerophthalmia. (See also Abst. 2304, Vol. 24).—I. Leitch.

1156

USBORNE, V. M. Hypochromotrichia on Ukara Island. *East African Med. J.*, 1954, **31**, 55-57. [E. African Med. Survey.]

On Ukara Island in Lake Victoria, depigmentation at the roots of the hair is seen among babies and toddlers of the Wakara but is much more common among the older children, especially the boys, whereas on the mainland, among the Wasukuma of Kwimba, it is most frequent in children under one year. In a survey of a small number of boys the percentage incidences in the 2 tribes on the island and mainland, respectively, were under 1 year 10 and 50, from 1 to 4 years 7.6 and 27, from 5 to 9 years 10 and 20, and from 10 to 14 years 30 and 10. No definite kwashiorkor was seen in either district. Both tribes have a small protein intake. Staples for the Wakara are cassava and millet with occasional fish and, for the Wasukuma, maize and millet with occasional meat. It is suggested that failure of pigmentation may not here be nutritional in origin.—E. M. Hume.

- DE WET, J. S. DU T. The association of under-nutrition and psychosis. *S. African J. Clin. Sci.*, 1954, 5, 97-107. [Tower Hosp., Fort Beaufort.]

In 12 months 142 non-European women were admitted to this mental hospital and 52 of them had signs of undernutrition. Full data are tabulated giving age, marital state and origin, whether rural or urban, of each patient and the duration of psychosis. Degrees were rated of wasting, oedema, bradycardia, hypotension, pellagrous desquamation, prurynoderma, dry skin, purpura, cracked lips, glossitis, increased tendon reflexes, nocturia, and polyuria, and the sum of these was translated into an undernutrition rating. Similarly, from degrees of confusion, emotional instability and visual hallucinations a rating for the organic-reaction syndrome was deduced. The extent of the increase in red blood cell sedimentation rate was also classified.

Wasting, dry skin and increase in red cell sedimentation rate were the commonest clinical findings. There was a high correlation between degree of undernutrition and the degree to which mental signs of organic-reaction type of psychosis were present, but, as both conditions in most patients were only mild, the correlation may not have much significance. The incidence was much greater among urban than among rural women. Psychoses likely to be attributable to vitamin deficiencies were thought to be the cause of less than 9 per cent. of the total admissions.—D. Harvey.

Vitamin A

1161

- KACAN, B. M. Vitamin A in health and disease. *Nat. Vitamin Found., Inc., N.Y., Nutrit. Symposium Ser. No. 7*, 1953, 31-45. [Med. Res. Inst., Michael Reese Hosp., Chicago, Ill.]

The absorption of vitamin A by infants and children was studied by giving 6000 I.U. per lb. in different forms, and estimating the level in the blood 3, 6 and 24 hr. later. Related experiments were made on animals.

In 3 groups of normal children aged 1 to 5 months, 6 to 12 months, and over 12 months, the efficiency of absorption of aqueous suspensions of either vitamin A alcohol or its palmitate increased with rising age. In the two younger groups, but not in the oldest, vitamin A alcohol was absorbed better than the palmitate. In a 7-month-old infant with cystic fibrosis of the pancreas an aqueous dispersion of vitamin A alcohol was absorbed much better than a dispersion of the palmitate, which was in turn better absorbed than natural esters from oily solution; with all forms of the vitamin the absorption was much below normal.

In dogs with ligated pancreatic ducts the defective absorption of vitamin A was improved, but not restored to normal, by the simultaneous administration of whole pancreas. Absorption of vitamin A palmitate or natural esters was not improved by pancreas.

In children with the nephrotic syndrome, in which the resting levels of vitamin A and of fat in the blood are high, all forms of vitamin A caused large increases which persisted after 24 hr. In specimens of liver obtained from such children at autopsy, high reserves of vitamin A were found. Similar high responses in the vitamin A level in the blood were observed in children suffering from excess of vitamin A, but no abnormality could be detected in the bones of nephrotic children.

In guinea-pigs in which reticulo-endothelial cells were blocked by injections of thorotrast and trypan red, the rise in blood vitamin A was greatly increased. The liver reserves, however, were lower than in normal animals which had been similarly treated. When abscesses were induced in rats by injections of turpentine or sweet almond oil, vitamin A decreased in the blood, but not in the liver. The absorption of vitamin A by rats was normal during 24 hr. after removal of both kidneys.—T. Moore.

- CORCOS, A., KORTOBI, M., and ZARKA-CORCOS, S. Xérophthalmie et kératomalacie chez les enfants en Tunisie. [Xerophthalmia and keratomalacia in children in Tunisia.] *Nourrison*, 1954, 42, 19-22. [Serv. Méd. Ophthalmol., Hôp. Sadiki.]

Every year, usually at the end of the summer, patients under 2 years of age are seen with severe signs of vitamin A deficiency in the eyes, and the condition makes a serious contribution to blindness in Tunisia. The children are usually cachectic

and dehydrated after repeated attacks of diarrhoea. Treatment is by intramuscular injection of vitamin A, 100,000 "units" or more daily, and instillation of the vitamin into the eyes. Antibiotics or antiseptics are not put into the eyes unless the indication for them is overwhelming. Prophylactic administration of vitamin A with other vitamins is recommended for the small child severely affected by diarrhoea.—E. M. Hume.

1163

OOMEN, H. A. P. C. **Xerophthalmia in the presence of kwashiorkor.** *Brit. J. Nutrition*, 1954, 8, 307-318. [Stella Maris Hosp., Macassar, Indonesia.]

In a hospital ward 44 Indonesian children, aged 7 months to 7 years, were selected as showing signs of advanced malnutrition. Xerophthalmia and keratomalacia, mostly severe, were present in 29 of them. The eye lesions were usually associated with retarded growth, and the other clinical findings often included respiratory infections, dysentery, oedema and lesions of the skin. Most of the livers were enlarged, and fatty infiltration, often with fibrosis, was found in specimens obtained by biopsy. Much the same picture was seen in specimens of liver taken from malnourished children without xerophthalmia. The diet of the children had consisted mainly of rice, with some green vegetables. Children from the Chinese community, who were better fed, did not have eye lesions. The eyes could usually be saved, even in children who later died from infection, by giving frequent doses of cod liver oil with a diet containing liver and green vegetables.—T. Moore.

BERGER, S. Wyniki badań nad zapasami akseroftolu (witaminy A), β -karotenu i sumy karotenoidów w wątrobie człowieka. [Results of some studies on the reserves of axerophthol (vitamin A), β -carotene and total carotenoids in human liver.] *Rocz. Państwowego Zakł. Hig.*, 1954, 5, 207-213. Russian and English summaries.

Estimations were made on the livers of 10 men and 4 women in normal health who had been killed in accidents. The average values in μ g. per g. fresh liver were for vitamin A 70.7, for β -carotene 1.2 and for total carotenoids 3.4. The range for total vitamin A activity was from 55.1 to 446.6 I.U. per g. The results are tabulated in full. (From English summary.)—D. Harvey.

1165

JACOBS, A. L., LEITNER, Z. A., MOORE, T. and SHARMAN, I. M. **Vitamin A in rheumatic fever.** *J. Clin. Nutrit.*, 1954, 2, 155-161. [Whittington Hosp., London.] Spanish summary.

Vol. 25, No. 1

Serial estimations were made of vitamin A and carotenoids in the blood plasma of patients with rheumatic fever and of patients with certain other diseases to serve as controls. Temperature and erythrocyte sedimentation rate were recorded. The patients were of both sexes and aged from 5 to 60 years. When the values for vitamin A and carotenoids were grouped according to body temperature the values for vitamin A were low at temperatures between 98.9° and 100° F., and still lower in patients with acute rheumatism at temperatures above 100° F. Carotenoid values, though always lower than those found in health, were affected only at temperatures above 98.9° F. in rheumatoid arthritis and erythema nodosum, and above 100° F. in acute rheumatism. For arbitrary ranges of the vitamin A values the corresponding mean erythrocyte sedimentation rates were calculated. For each disease, the vitamin A value fell with increasing sedimentation rate. When data for the rheumatic subjects were classified, according to the time since the inception of the disease, it was found that the vitamin A value returned to normal after about 4 weeks and the sedimentation rate after about 6 weeks. The temperature returned to normal after from 2 to 3 weeks and was subsequently subnormal. Re-investigation of results previously reported showed that the mean vitamin A reserve in the liver of children who died from heart disease, chiefly rheumatic, was 28 I.U. per g. compared with 129 I.U. for children who died from accident.—R. J. Ward.

1166

WANG, P., GLASS, H. L., GOLDENBERG, L., STEARNS, G., KELLY, H. G. and JACKSON, R. L. (with CHEN, J. Y. and DIMMITT, N. J.) **Serum vitamin A and carotene levels in children with rheumatic fever.** *Amer. J. Dis. Child.*, 1954, 87, 659-672. [Dept. Paediat., Coll. Med., State Univ. Iowa.]

Carotene and vitamin A were estimated in the fasting serum of 98 children, aged from 5 to 16 years, with rheumatic fever and associated disorders. Glycerol dichlorohydrin was used for estimating vitamin A. Patients were examined during the acute stage of the illness, during convalescence which was prolonged, and when the disease had become inactive after discharge from hospital. Low values for vitamin A, mean 32.1 μ g. per 100 ml. serum, were found in patients in the early, acute stage of rheumatic fever. The values rose steadily during the late acute and sub-acute stages and reached an average of 72.5 when the disease had recently become inactive. Corresponding mean carotene values rose from 58.2 to 179 μ g. per 100 ml. at the subacute stage and afterwards fell to 128. Low values for vitamin A, mean 32.0, were found also in the blood of patients

with advanced cardiac decompensation and enlargement of the liver; in patients with severe cardiac damage with enlargement of the liver, the mean value was 39.3; in patients with upper respiratory infections and in others with acute exacerbations of the rheumatic process the vitamin A value was low.

Daily administration of corticotropin to 14 children produced a small increase in the serum vitamin A value. Larger increases occurred after 5 days of treatment, the highest values observed being 145, 188 and 210; the average vitamin A value was 92.6, which was 20 μ g. higher than the average value for patients in whom the disease had recently become quiescent. The rise induced by corticotropin was observed at all stages of the disease.

In absorption tests vitamin A equivalent to 6000 I.U. per lb. bodyweight was given in oil or as an aqueous preparation to 46 children. Four hours later, 19 of 28 values for patients receiving the aqueous preparation were above 400 μ g. per 100 ml.; only 6 of 23 values for those receiving the oily preparation were above that level.

It is recommended that the diet of children with rheumatic fever should be supplemented with from 3000 to 5000 I.U. vitamin A daily.—I. M. Sharman.

MENDELOFF, A. I. **The effects of eating and of sham feeding upon the absorption of vitamin A palmitate in man.** *J. Clin. Invest.*, 1954, 33, 1015-1021. [Nutrit. Res. Lab., Dept. Prevent. Med., Sch. Med., Washington Univ., St. Louis, Mo.]

Of 16 normal fasting subjects, 5 showed no appreciable rise in the value for vitamin A in the serum during the 8-hr. period after an oral test dose of 100,000 μ g. vitamin A palmitate dissolved in maize oil, but when a meal was taken 2 hr. after the test dose a marked rise occurred in all the subjects. Blood specimens, collected before and 2, 2½, 3 and 4 hr. after the test dose showed average values, for 14 of the subjects, of 43, 126, 241, 442 and 402 μ g. per 100 ml. serum.

In a second group of 16 normal subjects, and 32 hospital patients whose illness was unlikely to affect fat absorption, similarly investigated, an appreciable rise began in the serum value for vitamin A after a meal which was taken 2 hr. after the test dose. When vitamin A was administered by stomach tube into the duodenum of 6 normal

subjects only a small rise in the serum value occurred during the ensuing 4 hr. if the subjects fasted, but when they were allowed to eat immediately after the dose a significant increase resulted. Further studies with 3 totally gastrectomised subjects showed that the presence of the stomach, and presumably of its acid and peptic secretions, was not necessary for the effect. It is suggested that "the lacteals may be activated in some way by eating to expel their contained vitamin A into the bloodstream". Another experiment, in which 5 subjects thoroughly masticated and expectorated an attractive meal, showed that sham feeding was almost as effective as normal eating in activating the mechanism. To study the effect of an anticholinergic agent, 1.0 mg. atropine sulphate was given by intramuscular injection to 4 subjects 100 min. after the dose of vitamin A. They ate their breakfast 20 min. after administration of atropine, but the rise of vitamin A in the blood was delayed until 4 hr. after the dose of vitamin A had been given.—I. M. Sharman.

1169

MARIE, J. and SÉE, G. **Acute hypervitaminosis A of the infant. Its clinical manifestation with benign acute hydrocephalus and pronounced bulge of the fontanel; a clinical and biologic study.** *Amer. J. Dis. Child.*, 1954, 87, 731-736. [Hôp. Enfants-Malades, Paris 15.]

In 3 infants, aged 3, 3½ and 7½ months, the occurrence of vomiting and a mushroom-like protuberance of the anterior fontanelle was found to be associated with the ingestion of 350,000 I.U. vitamin A and 300,000 I.U. vitamin D during the preceding 12 to 24 hr. The swelling was temporary, and the infants soon recovered. In several other infants, aged from 24 days to 15 months, sickness and hydrocephalus could usually be produced by large doses of natural vitamin A without vitamin D; the severity of the disorders was not related to the degree of bulging of the fontanelle. Synthetic vitamin A apparently did not cause hydrocephalus. Estimation of vitamin A in the blood plasma at intervals showed that the highest values were not associated with the most bulging fontanelles. Cerebrospinal pressure was raised slightly during hydrocephalus, and the fluid was clear and devoid of vitamin A.

Acute hydrocephalus was produced also in a 4-month-old puppy which was given a single oral dose of 350,000 I.U. vitamin A.—T. Moore.

1170

GERBER, A., RAAB, A. P. and SOBEL, A. E. **Vitamin A poisoning in adults. With description of a case.** *Amer. J. Med.*, 1954, 16, 729-745. [Dept. Med., Jewish Hosp., Brooklyn, N.Y.]

For over 8 years a 28-year-old white woman

N.A. and R., January 1955

continued to take 500,000 I.U. vitamin A daily as treatment for ichthyosis. During the period she was admitted to hospital ten times, usually complaining of headaches, diplopia, arthritis and pruritus. Many diagnoses were made, including brain tumour, serous meningitis, virus radiculonephalitis, psychoneurosis and generalised infectious arthritis. X-ray examinations showed disturbances of calcification, including calcification of the intrapatellar ligaments. Finally estimation of vitamin A in the blood plasma gave a value of 2000 μg . per 100 ml., believed to be the highest value ever recorded. Poisoning from excess of vitamin A was diagnosed, and treatment with it was stopped. The value for vitamin A in the plasma fell slowly, but was still above the normal range after 3 months. At the same time, clinical improvement in the neurological, skeletal and skin manifestations proceeded rapidly and the patient became fit for discharge from hospital.—T. Moore.

1171

KLEINE, H. O. and HUBER, L. Zur Frage der Hypervitaminisierung mit Vitamin A und Vitamin C bei inoperablen Karzinomen nach v. Wendt. [On the treatment of inoperable carcinoma with excess of vitamin A and vitamin C as suggested by v. Wendt.] *Münch. med. Wochenschr.*, 1954, **96**, 367-370. [Frauenklinik, Städt. Krankenhaus, Ludwigshafen am Rhein.]

The literature is reviewed, and von Wendt's claims (*Ztschr. ges. inn. Med.*, 1949, **4**, 267; 1950, **5**, 255; 1951, **6**, 255) of the benefits derived in inoperable carcinoma from daily doses of 300,000 I.U. vitamin A and 2 g. vitamin C are criticised.

E. M. Hume.

Vitamin D

1172

OSTER, H. Beeinflussen unsere Massnahmen gegen die Rachitis den Durchbruch der Milch- und der bleibenden Zähne und den Fontanellschluss? [Do the antirachitic measures which we take affect the appearance of the milk or permanent teeth, or the closure of the fontanelle?] *Ztschr. Kinderheilk.*, 1954, **74**, 582-592. [Gesundheitsamt Stadt Nürnberg.]

In Nürnberg, the age in months of the appearance of the 1st, 2nd, 3rd, 4th, 6th, 8th, 12th, 19th, and 20th milk tooth was noted for groups of from 97 to 462, in all about 2000, children in 1938, and for comparable numbers, in all about 2500, in 1950, when it was considered that prophylaxis of rickets had been much more effective. There was no difference between the years in the earliest, latest or average date for the appearance of any of the teeth except the lower median incisors, which appeared on the average 1 month earlier in 1950.

Comparison of the date of closure of the [grosse: anterior] fontanelle of 543 children before institution of intensive rickets prophylaxis, and of 583 after it, showed a range of dates from the 5th to the 26th month for the first group, and from the 3rd to the 26th month for the second, with larger percentages at earlier, intermediate dates in the second group. The age at which the "six-year" molars were present was determined for 620 boys and 462 girls in Nürnberg in 1953, and compared with results of observations in Frankfurt a.M. by Bauer (*Inaugural Dissertation*, Frankfurt, 1927) in 1927 and by Franz (*Inaugural Dissertation*, Frankfurt, 1938) in 1938. The average dates were very appreciably earlier in 1938 than in 1927. In Nürnberg in 1950 they were intermediate; the date for girls was earlier than for boys. Dates were established for the appearance of other permanent teeth in boys and girls in Nürnberg in 1950.—E. M. Hume.

1173

BACH, U. Das Verhalten der alkalischen Serum-Phosphatase bei Frühgeborenen, Rachitikern und Spasmophilen. [Alkaline serum phosphatase in premature infants and infants with rickets and spasmophilia.] *Ztschr. Kinderheilk.*, 1954, **74**, 593-609. [Kinderkrankenhaus Bethel, bei Bielefeld.]

Estimation of alkaline serum phosphatase was used as criterion for assessing the antirachitic efficacy of Vigorsan, which is a water-soluble preparation of vitamin D₂ adsorbed on milk protein. The method used was that described by Hövels and Laun (Abst. 1318, Vol. 23). Of the units used in expressing the results, 3.5 equalled 1 Bodansky unit.

The average value from 400 estimations on 40 children without rickets in 1953 was 28.6 for January to March, and 21.6 for April to June.

For 22 children with rickets in the same period the mean value was 55.5. All of them were given a dose of 5 mg. vitamin D₂ as Vigorsan on 3 successive days. The phosphatase values decreased slowly, the mean value being 48 after about 10 days, and 39.5 after about 25 days. Six babies with spasmophilia as well as rickets had values ranging from 135 to 500; on treatment the values decreased rapidly and after 10 days ranged from 39 to 165.

The mean value for 20 premature infants born in the first half of 1953 and aged about 5 weeks was 55.1. The children were given small daily doses of 0.025 mg. vitamin D₂ as Vigorsan, and the phosphatase value slowly fell to a mean value of 47 at about 3 months of age. Prevention of rickets, including craniotabes, was best obtained in premature infants with a single dose of 5 mg. vitamin D₂ as Vigorsan followed by the small daily

doses. The results were much more satisfactory than those obtained in previous years with Vigantol.

The vitamin was not easily separated from the milk protein to which it was attached, even by repeated shaking with ether.—E. M. Hume.

JONXIS, J. H. P. and HUISMAN, T. H. J. **The renal element in rachitic amino-aciduria.** *Lancet*, 1954, **267**, 513-516. [Kinderklin., Acad. Ziekenhuis, Groningen.]

Individual amino-acids were estimated by ion-exchange chromatography with Dowex 50 in the plasma and urine of 2 children aged about 8 and 4 years with resistant rickets, of 1 aged 1 year with florid rickets, and of 3 normal children, before and after intravenous infusion of histidine, 404 or 267 mg., and arginine, 416 or 275 mg. No vitamin D was given till later. The percentage excreted of the histidine was 33, 25 and 16 by the rachitic children, and 3.6, 5.0 and 2.1 by the normal children. The high excretion by the rachitic children was not due to a higher concentration in the blood, and is ascribed to a disturbance of tubular re-absorption. There was no difference in the amounts of arginine excreted, but the rachitic children had lower values for blood arginine both before and during infusion. The amino-acids threonine, serine, lysine and glycine, and in one child tyrosine, were somewhat increased in the urine of the children with resistant rickets after administration of arginine and histidine. The first 4 are among those whose amount was previously found to be increased in the urine of children with rickets (Abst. 1137, Vol. 24). It is considered probable that increased tubular re-absorption of histidine interferes with the re-absorption of these other amino-acids.

WINBERG, J., BERGSTRAND, C. G., ENGFELDT, B. and ZETTERSTRÖM, R. **Primary vitamin D refractory rickets. I. Report of two cases treated with high doses of vitamin D.** *Acta paediat.*, 1954, **43**, 347-361. [Paediat. Clin., Karolinska Sjukhus, Stockholm.] French, German and Spanish summaries.

The two patients were boys of 3 and 6 years. The disease eventually yielded to very large amounts, many million I.U., of vitamin D. The disease is called primary vitamin D refractory rickets because its cause remains obscure and no evidence was found of excessive loss of P in the urine through failure of tubular re-absorption by the kidneys, such as is reported for another type of vitamin-D-resistant rickets.—E. M. Hume.

1176

RUPP, W. and SWOBODA, W. **Untersuchungen des PO_4 -Stoffwechsels bei vitamin-D-resistenter Rachitis ("Phosphat-Diabetes").** 1. [Phosphate metabolism in rickets resistant to vitamin D, "phosphate diabetes". 1.] *Helv. paediat. Acta*, 1954, **9**, 249-257. [Kinderklin., Univ. Vienna.] French, Italian and English summaries.

In 5 children aged from 5 to 11 years with resistant rickets, 1 with deficiency rickets, and some without rickets, estimation was made of inorganic P and Ca in the blood serum and urine, of the clearance of inorganic P, and of the extent of glomerular re-absorption, with and without previous intravenous administration of a mixture of mono- and disodiumphosphate. All the findings supported the interpretation of resistant rickets as due to failure in tubular re-absorption of P by the kidney. It is considered that the defect may be in the tubules themselves, or in an abnormal increase in the response of the parathyroid gland to counteract the high level of P in the serum.—E. M. Hume.

1177

SEIDEL, M. **Ein Beitrag zu renal bedingten Knochenveränderungen im Kindesalter (sog. renale Rachitis). [Bone changes of renal origin in childhood (so-called renal rickets).]** *Frankfurter Ztschr. Pathol.*, 1954, **65**, 259-270. [Pathol.-Bacteriol.-Serol. Inst., Städt. Krankenhaus, Karlsruhe.]

Bone changes resistant to Ca and Vigantol in a boy of 5 are discussed in conjunction with the literature on renal rickets. It is suggested that this misleading term be dropped and replaced by "infantile renal osteodystrophy".—W. M. Deans.

LOWE, K. G., HENDERSON, J. L., PARK, W. W. and MCGREAL, D. A. **The idiopathic hypercalcaemic syndromes of infancy.** *Lancet*, 1954, **267**, 101-110. [Dept. Med., Univ. St. Andrews.]

It is considered that there may be 2 similar syndromes of idiopathic hypercalcaemia in infancy. Detailed descriptions are given of a child ill from 4, and severely ill from 10, months when first seen and since dead, and of 6 infants less ill and all fully or partly recovered. The typical onset was with vomiting, constipation, anorexia and arrest of

growth. The children became hypotonic and apathetic. Blood Ca and urea were high; there was sometimes renal and other infection such as colds, bronchitis, tonsillitis, and otitis. Biopsy of the kidney of the severely ill child did not suggest chronic nephritis but there were deposits of Fe and Ca. The biopsy findings were confirmed at autopsy; no abnormality of the parathyroid glands was found. Bone was sclerotic.

All but one of the children had been fed on National Dried Milk and the exception too was artificially fed. All but one had had additional cod liver oil and all but one had been given magnesium intermittently or regularly. Treatment was with unfortified milk, without other source of vitamin D and without alkali. Clinical improvement was rapid but biochemical recovery was still incomplete in 4 at the most recent examination.

It is suggested that the syndrome may be caused by over-absorption of Ca from cow's milk fortified, and sometimes further supplemented, with vitamin D, possibly in association with an oversensitivity to vitamin D.—I. Leitch.

1180

CRIBERY, R. D. G. and NEILL, D. W. **Idiopathic hypercalcaemia in infants with failure to thrive.** *Lancet*, 1954, **267**, 110-114. [Royal Hosp. Sick Child., Belfast.]

Clinical and biochemical data are described for 16 infants in whom the syndrome was as described in the preceding Abst. All were fed on cow's milk; 15 on dried milk fortified with vitamin D. Two infants had no additional vitamin D; the others had additions of from 400 to 1600 I.U. daily so that, in all, 2 had about 700, 6 had from 1100 to 1600, 7 had from 1800 to 2400 and 1 had 3200 I.U. daily. Only 7 had alkali or magnesium.

At first examination blood Ca was above normal, and up to 17 mg. per 100 ml. Blood urea was almost always high, and the mean was 54 mg. per 100 ml. Inorganic P was within the normal range. The urine was sterile in only 4 of the children. X-ray photographs of the bone were normal in 3 and showed abnormal density in 12.

Treatment was with unfortified milk or a low-Ca diet of soya flour, glucose, peanut oil and arrow-root. On re-examination after intervals of from 1 to 18 months only 4 had regained a normal rate of growth; 8 remained small and 4 of them continued to show high blood urea; 4 were still in the same characteristic abnormal state.

The syndrome is attributed to over-absorption of Ca. Balance studies were attempted but, on account of vomiting, were successful with 2 infants only. Without added vitamin D, retentions were 57 and 56.7 per cent. of intake. It is considered that unnecessarily large amounts of vitamin D should be discouraged.—I. Leitch.

1181

MAROLDA, C. I. **Influencia de la vitamina D en la absorcion rectal del calcio. [Effect of vitamin D on absorption of calcium from the rectum.]** *Rev. Asoc. méd. argent.*, 1954, **68**, 171-173.

Ca was estimated in the blood of 3 groups of from 7 to 10 patients before, and 2.4 or 8 hr. after, administration of a suppository containing 0.75 g. Ca gluconate, 0.25 g. Ca ascorbate and 5000 I.U. vitamin D. The serum values in mg. per cent. ranged before treatment from 8.5 to 12.6 and after treatment from 8.8 to 13.2. In 2 patients there was no change, in 3 there was a small decrease, and in the remainder there was a small rise ranging in amount from 0.2 to 3.2 mg. per cent. The extent of the increase did not depend on the initial value.—E. M. Hume.

Vitamin E

1182

RABOCH, J. and ZÁHOŠ, Z. **Význam výživy pro mužskou plodnost. (2. Shlediska biopsií varlat.) [Importance of nutrition for male fertility. 2. From the point of view of biopsy of the testicles.]** *Čas. Lék. čes.*, 1954, **93**, 406-412. [Sexol. Inst., Karl's Univ., Prague.] English and Russian summaries.

For part 1 see Abst. 2609, Vol. 21.

Of 240 biopsies of human testicles, 33 were selected as being from subjects with a history of disturbed fertility where the man was the last or last but one of a large family. The most frequent histological findings were that the seminiferous ducts contained only Sertoli cells, and that the diameter of the tubules was less than normal. Possible causes are discussed, among which malnutrition during development is considered important. (From summary).—E. M. Hume.

1183

DARWISH, M., EL-ETRYBY, A. and EL-SHEBINTI, A. **The treatment of male sterility by low dose pituitary irradiation with reference to the value of vitamins A and E.** *J. Egypt. Med. Assoc.*, 1954, **37**, 124-127. [Kasr El Einī Fac. Med., Cairo.]

Treatment of 16 patients by irradiation [presumably with X-rays] of the pituitary gland, with vitamins A and E, and with hormones, separately or together, gave no conclusive result. There was a slight suggestion that the vitamins were helpful.

1184

OVERMAN, R. S., MCNEELY, J. M., TODD, M. E. and WRIGHT, I. S. **Effects of vitamin E preparations on plasma tocopherol levels.** *J. Clin. Nutrit.*, 1954, **2**, 168-178. [Dept. Med., Cornell Univ. Med. Coll., New York.] Spanish summary.

Tocopherol was estimated spectroscopically in the plasma of 23 active adults, aged from 26 to 36 years, before and after taking *dl*- α -tocopheryl acetate orally as one of 2 aqueous emulsions containing 100 mg. per ml., or as capsules or tablets containing 100 mg. In studies before treatment estimations were made on 10 successive days at 9.30 a.m. and at other times on the same day. The mean tocopherol concentration of 50 plasma samples taken at 9.30 a.m. was 1.002 mg. per cent. with range from 0.46 to 1.77. Analysis of variance of the results at 9.30 and 11.30 a.m., and 1.30 and 3.30 p.m., showed that the variation was not significantly greater than would be expected on the basis of variation of the values at each point of time.

In single-dose studies plasma tocopherol was estimated at intervals up to 72 hr. after giving 100, 200, 400 or 500 mg. A significant increase in the value for free tocopherol in the plasma was found after 6 hr. with all the doses except sometimes the smallest. In further studies tocopherol values were estimated after prolonged treatment with the different preparations of tocopherol. Repeated daily doses resulted in a larger maximum increase than was found after a single dose of the same order; thus, with doses of 400 mg. tocopherol in capsule form mean values of 1.19 and 1.83 mg. per cent. were found after 1 and 12 days, respectively.

When *dl*- α -tocopherol as the free alcohol or as the monosodium phosphate was administered parenterally to 15 convalescent hospital patients of ages from 40 to 60 years there was no apparent increase of free tocopherol in the blood plasma, whether oil or water was used as the vehicle for injection.

PAUL, R. M., LEWIS, J. A. and DELUCA, H. A.
The lack of effect of vitamin E on the blood clotting mechanism. *Canad. J. Biochem. Physiol.*, 1954, **32**, 347-353. [Westminster Hosp., London, Ont.]

Eleven male patients who had no illness or treatment likely to affect the blood clotting mechanism were studied for a period of 10 days. On each of the first 3 days blood was taken, and clotting and prothrombin times, platelet counts, fibrinogen and vitamin E content were estimated; the clotting times were estimated in duplicate in glass and silicone-treated tubes. During the following 7 days, 6 of the patients were given 600 mg. α -tocopheryl acetate daily; the remaining 5 patients received a dummy preparation. Similar examinations of the blood were made on each of the last 3 days. The average value for vitamin E in the blood of the patients given tocopherol rose from 0.87 mg. to 1.55 mg. per cent.; the corresponding values for those given dummies were 0.78

and 0.76 mg. A slight increase in clotting time, as measured in both glass and silicone-treated tubes, was found for the patients receiving dummies. A similar but smaller increase occurred in the patients given vitamin E, but on statistical analysis the difference in the presence or absence of vitamin was found not significant. No change in prothrombin time attributable to vitamin E was found. The fibrinogen values ranged from 463 to 482 mg. per cent. and were somewhat above those normally found in healthy subjects, but no change resulted from the administration of vitamin E. A slight rise in the mean platelet count, in thousands per c.mm., from 235.2 to 273.8 occurred in patients given vitamin E, but statistically, the difference, compared with that of the subjects given dummies, was of borderline significance, $P = 0.05$. The amount of vitamin E given was comparable with that usually given for therapeutic purposes, but it was relatively less than that reported in the literature as having been given in similar studies with experimental animals, which yielded different results.—I. M. Sharman.

1186

MACKENZIE, J. B. **Relation between serum tocopherol and hemolysis in hydrogen peroxide of erythrocytes in premature infants.** *Pediatrics*, 1954, **13**, 346-351. [Dept. Paediat., Div. Chem. Embryol., Univ. Colorado Sch. Med., Denver.]

Twenty-one premature infants of gestational age from 23 to 36 weeks, born at or referred to Colorado General Hospital, were reared on powdered, half-skimmed cow's milk. Small blood specimens were collected at intervals during the first 2 months of life from heel prick punctures. The red cells were examined for resistance to haemolysis by H_2O_2 according to György's test, and serum tocopherol was estimated by a micro-method. The results of the tests for haemolysis were compared with those of tests with blood from adult donors and from rats deprived of vitamin E.

Tocopherol values in the infants' sera, which averaged 0.34 mg. per 100 ml. during the first 10 days of life, fell to about half that value, from 0.20 to 0.17, during the remainder of the 2 months' study. Wide fluctuations in the percentage haemolysis, from 9 to 98, were found; the percentage was not related inversely to the tocopherol content. For instance, 2 infants of comparable weight and age showed 17 and 73 per cent. haemolysis though their serum tocopherol values were almost identical, namely, 0.14 and 0.16 mg. per 100 ml. Five of 6 infants given 2.5 or 5.0 mg. α -tocopheryl acetate daily responded with a dramatic rise of the vitamin in the blood to values ranging from 0.5 to 2.3 mg. per 100 ml., and with high resistance of the red cells

N.A. and R., January 1955

to haemolysis. It was found that liability to haemolysis disappeared almost completely when the serum tocopherol value was above 0.5 mg. per 100 ml., and completely when it was above 1.0 mg. It appears, therefore, that in premature infants the concentration of tocopherol in the serum is of critical importance. It is suggested that infants artificially fed should be given the small amounts of tocopherol necessary to raise the tocopherol in the blood above the critical value.

I. M. Sharman.

1187

BECKMANN, R., FELDMANN, F. and SCHÜMMEL-FEDER, N. Erythroblastose-Probleme. Verhalten von Rh-Antikörpertiter und Serum-Tocopherol-Gehalt sowie deren Beziehungen zu feingeweblichen Plazentaveränderungen bei der fötalen Erythroblastose. Zugleich ein Beitrag zur Erythroblastose-Propylaxe mit Vitamin E. [Erythroblastosis problems. Behaviour of the Rh antibody titre and serum tocopherol content and their relation to histological changes in the placenta in foetal erythroblastosis; a contribution to the prevention of erythroblastosis with vitamin E.] *Deutsch. med. Wochenschr.*, 1954, **79**, 1157-1162. [Kinderklin., Westfäl. Wilhelms Univ., Münster.]

Studies were made of the antibody titre and vitamin E content of the blood during pregnancy, and of the condition and viability of the foetus, in 19 women, mostly Rh-negative, whose offspring were expected to have erythroblastosis. Five of the women were given 100 mg. *dl*- α -tocopheryl acetate daily from the 2nd or 3rd month of pregnancy, and one from the 7th month. The placentas were examined histologically. No relation was found between the severity of erythroblastosis and the concentration of antibody or vitamin E in the blood. The degree of abnormality in the placenta also appeared to be unrelated to the severity of erythroblastosis. It is claimed, however, that the abnormalities in the placenta tended to be slight in the women who had been given tocopherol.—T. Moore.

1188

ROMEO, F. and PARRINELLO, A. Influenza della vitamina E sul ricambio glucidico. [Influence of vitamin E on carbohydrate metabolism.] *Acta vitaminol.*, 1954, **8**, 129-134. [Ist. Patol. Spec. Med., Univ. Messina.] French, English, German and Spanish summaries.

The glucose tolerance curve and the sugar content of the 24-hr. urine were estimated before and after 10 days' oral treatment with 200 mg. vitamin E daily, in 10 normal subjects and 10 subjects with diabetes. In the normal subjects there was no effect. In the diabetic subjects the

glucose tolerance curve was to some extent favourably modified, and glycosuria is reported as diminished.—E. M. Hume.

1189

GOUNELLE, H., MARNAY, C. and RABII, H. L'action hypoglycémiant de la vitamine E chez le sujet normal et diabétique. [The effect of vitamin E in lowering blood sugar in normal and diabetic subjects.] *Presse méd.*, 1954, **62**, 888-890. [Centre Recherches Foch, Paris.]

In human subjects who were given 10 g. olive oil mixed with 10 g. *dl*- α -tocopheryl acetate, an enormous dose, the level of glucose in the blood fell by about 10 per cent. during the next 4 hr. When the tocopherol was given 4 hr. before 200 g. glucose, the rise in blood sugar during the next few hours was much less than in a similar test without tocopherol made at another time. Olive oil, given without tocopherol, raised the blood sugar. In diabetic subjects tocopherol decreased the transitory rise in blood glucose which immediately followed the injection of slow-acting insulin. In rabbits which had been injected with alloxan, subsequent massive oral doses of tocopherol reduced the rise of blood sugar and the toxic effects.—T. Moore.

Vitamin B Complex

1190

LINDGREN, I. M. K metodike ustanovleniya diagnoza nedostatochnosti vitamina B₁. [Method of diagnosing vitamin B₁ deficiency.] *Klin. Med., Mosk.*, 1953, **31**, No. 8, 42-46. [Klin. Kozh. Vener. Bolezni, Moscow.]

Vitamin B₁ in the urine and pyruvic acid in the blood and urine were estimated for 11 normal subjects and 30 patients with psoriasis, before and after a test dose of the vitamin.

In the normal group having a diet deemed adequate in vitamin B₁, the average amount in the urine in 24 hr. was 442 μ g.; pyruvic acid values in blood and urine were 0.5 and 0.54 mg. per cent., respectively. After the test dose, 31 per cent. of the vitamin was excreted in 4 hr. and 36 per cent. in 24 hr.

The 30 patients with psoriasis had a dietary intake of 2700 μ g. vitamin B₁ in 24 hr. and were given repeated intramuscular injections of 10 mg. daily for from 10 to 30 days. Of 19 showing improvement or cure, 7 excreted little vitamin B₁ before the test and retained most of that administered, and 12 had a high rate of urinary excretion before the test and excreted on an average 23 per cent. of that given in 4 hr. and 38 per cent. in 24 hr. They had a high pyruvate value in blood and urine, from 1.18 to 3.0, and from 1.37 to 3.92, mg. per cent., respectively. Of 11 who showed no improvement, 10 had normal values for urinary

excretion of vitamin B₁ and for blood and urine pyruvate. In the 11th case, the pyruvate values were high.

It is concluded that the urinary excretion of vitamin B₁ is not an adequate criterion of deficiency and should be studied in conjunction with pyruvate values in blood and urine and the clinical and biochemical responses of the patient to administration of vitamin B₁.—D. W. Taylor.

1191

DERVIZ, G. V. Diskussionnye zamechaniya k stat'e I. M. Lindgren "K metodike ustanovleniya diagnoza nedostatochnosti vitamina B₁". [Discussion on I. M. Lindgren's article, "Method of diagnosing vitamin B₁ deficiency"] *Klin. Med., Mosk.*, 1953, 31, No. 10, 85-86.

A critical discussion of certain implications of the data mentioned in the preceding Abst.

D. W. Taylor.

AGAPOVA, O. I. Vliyaniye vitamina B₁ na ustoiichivost' zubov k kariesu. [The effect of vitamin B₁ on resistance of teeth to dental caries.] *Stomatologiya*, 1954, No. 1, 17-19. [Moscow Med. Stomatol. Inst.]

Seventy-five children received 2 mg. vitamin B₁ daily with their ordinary food which was calculated to contain from 0.6 to 0.7 mg., and 75 received no addition. At the end of 1½ months 25 children in the group having the vitamin had 59 carious teeth and 28 children not receiving the extra vitamin had 69. After a further 4 months those having the vitamin had only 3 more teeth affected and no other child in the group had developed caries; in the untreated group 5 more teeth were affected and 3 more children had developed caries. Some children were lost to both groups in the course of the observation.—H. Scherbatoft.

1193

RUIZ, M. Los megaorganos digestivos por avitaminosis B₁. [Enlarged digestive organs in vitamin B₁ deficiency.] *Rev. clín. española*, 1954, 53, 182-188. [Madrid.]

The occurrence of enlargement in the oesophagus and intestine, especially in the ascending colon, of patients suffering from deficiency of vitamin B₁, is discussed and illustrated by X-ray photographs from 3 patients. Treatment for several months with very large amounts of vitamin B₁ with other vitamins restored the picture almost to normal. Patients with such intestinal enlargements were not seen after the nutritional condition of the country improved at the end of the civil war.

TRULSON, M. F. FLEMING, R. and STARE, F. J. Vitamin medication in alcoholism. *J. Amer.*

Med. Assoc., 1954, 155, 114-119. [Dept. Nutrit., Harvard Sch. Pub. Health, Boston, Mass.]

In addition to such other treatment as might be necessary patients were given a multiple vitamin preparation or a dummy; 82 patients were kept under observation for 6 months, 58 receiving the vitamins and 24 the dummy. The number of patients who became totally abstinent was greater in the group having the dummy, but more patients improved in their drinking habits in the group having vitamins. A change of treatment from dummy to vitamins led to greater improvement than the reverse change. The results did not convincingly suggest benefit from the vitamin treatment but were considered sufficiently encouraging to warrant further trials.

RAMUNNI, M. Influenza del salicilato di sodio sulla eliminazione urinaria di aneurina. [Influence of sodium salicylate on urinary excretion of vitamin B₁.] *Acta vitaminol.*, 1954, 8, 164-166. [Ist. Clin. Med., Univ. Bari.] French, English, German and Spanish summaries.

Vitamin B₁ was estimated in the urine of 12 adults for 2 days before, and for 3 days during, oral administration of 8 g. sodium salicylate. There was no significant effect.—E. M. Hume.

N.A. and R., January 1955

1199

BARBIERI, L. L., MARZOCCHI, G., RUMPIANESI, G. and BRUNELLI, M. A. Röntgenstimolazione della tiroide ed eliminazione urinaria della tiamina, della riboflavina, della niacina, dell'acido ascorbico e dei 17-ketosteroidi. [X-ray stimulation of the thyroid gland and excretion in the urine of vitamin B₁, riboflavin, nicotinic acid, ascorbic acid and 17-ketosteroids.] *Internat. Ztschr. Vitaminforsch.*, 1954, 25, 261-274. [Ist. Clin. Med. Gen., Univ. Bologna.] German, French and English summaries.

Of 15 patients of both sexes, aged from 20 to 34 years, convalescent from illnesses not involving the endocrine glands, 10 were given X-ray irradiation of the thyroid gland and 5 of the thigh. Certain substances were estimated in the 24-hr. urine on the day before irradiation and for the next 2 days.

After irradiation of the thyroid gland, the amount in the urine of vitamin B₁, ascorbic acid and 17-ketosteroids was increased, that of riboflavin and nicotinic acid was reduced. After irradiation of the thigh there was no constant change.—E. M. Hume.

1200

HORWITT, M. K. Report of Elgin Project No 3 with emphasis on liver dysfunction. *Nat. Vitamin Found., Inc., N.Y., Nutrit. Symposium Ser. No. 7*, 1953, 67-83. [Biochem. Res. Lab., Elgin State Hosp., Ill.]

Elgin Project No. 3 is a study of man's needs for nicotinic acid and tryptophan in diets adequate or deficient in riboflavin. In this partial report attention is given mostly to changes which occur in liver function as a consequence of dietary deficiency which is probably not associated with nicotinic acid but which, like kwashiorkor, responds to treatment with liberal amounts of animal protein.

The basal experimental diet supplied 2300 Cal., 6.5 g. protein N, 93 g. fat, 5.8 mg. nicotinic acid, 265 mg. tryptophan and 414 µg. riboflavin. The diet will be described in detail elsewhere but it is stated that maize meal was not included and sources of protein mentioned are zein, flour [kind not stated] and gelatine. Supplements of vitamins A, B₁, B₆, B₁₂, C and D, Ca pantothenate, folic acid, biotin, dicalcium phosphate and ferrous sulphate were given. No supplement of vitamin E was given but the basal diet contained 40 g. margarine. Forty subjects were divided into 5 groups. Four of these groups received the basal diet with one of the following supplements daily: 0.1 mg. riboflavin; 2 mg. riboflavin; 2 mg. riboflavin and 10 mg. nicotinic acid; 2 mg. riboflavin and 50 mg. L-tryptophan increased to 100 mg. after 10 weeks. The fifth group had hospital diet to appetite.

Vol. 25, No. 1

There was no sign of pellagra; signs of riboflavin deficiency were seen in 6 of the 8 subjects receiving only 0.5 mg. riboflavin daily.

When the experimental diet supplemented with tryptophan and riboflavin was given to weanling rats, growth was retarded and livers showed intense fatty infiltration. These effects were counteracted by the addition of lactalbumin to the diet.

In the study of the human subjects all persons on the experimental diets showed raised levels of blood lactic and pyruvic acids after 7 weeks. Clinical evidence of liver enlargement was found in some of the subjects after 5 months. A number of liver function tests were made with negative results but the bromosulphalein retention test indicated abnormal function in some of the subjects.

During the second year of the experiment supplements such as methionine, choline and lactalbumin (30 g. daily) were given or the subjects were given hospital diet. Of these treatments only hospital diet reduced liver size and the levels of lactic and pyruvic acids in blood. Both 30 g. lactalbumin and hospital diet caused improvement in bromosulphalein retention time.—F. C. Aitken.

KOKIL, S. Über Dermatitis seborrhoides. [Seborrhoe dermatitis.] *Ann. paediat.*, 1954, 183, 28-32. [Kinderabt., Zentralkrankenhaus d. Arbeiter-Krankenkasse, Afula, Israel.] English and French summaries.

Dermatitis seborrhoides of the young infant is a characteristic disease, occurring in the first 3 months of life. It has no relation to allergic eczema of infants, or to *dermatitis seborrhoides* of older children and adults. It occurs in the months from November to April, and is thought probably due to diminution in the amount of biotin in human and cow's milk at that season, so that the infant's biotin intake is not sufficient to ensure normal keratinisation of the epidermis. Biotin is reported to be a specific cure in an amount of 5 mg. daily given orally or parenterally. Whether the dermatitis was recent or of longer standing, cure was achieved in from 2 to 3 weeks, but biotin was without effect in similar affections of older children.—M. B. Richards.

WACHSTEIN, M. and LOBEL, S. Abnormal tryptophan metabolites in human pregnancy and their relation to deranged vitamin B₆ metabolism. *Proc. Soc. Exp. Biol. Med.*, 1954, 86, 624-627. [Div. Labs., St. Catherine's Hosp., Brooklyn, N.Y.]

When a dose of 10 g. *dl*-tryptophan was given to 4 non-pregnant women and to 11 women on the first or second day after delivery, the average excretion of xanthurenic acid in mg. during the next 24 hr. was 16 in the first group and 183 in the second. Paper chromatography of samples of urine showed that the non-pregnant women excreted kynurenine, kynurenic acid and *N*- α -acetylkynurenine; in the urine of the women just after delivery many other tryptophan metabolites appeared, including 3-hydroxykynurenine, which formed a pattern similar to that found in rats deprived of vitamin B₆; administration of 50 mg. pyridoxine hydrochloride somewhat reduced the amounts excreted. It is suggested that deficiency of vitamin B₆ may be induced in pregnancy by the demands of the foetus for the vitamin.

1206

FINKB, H. Über die Behandlung des Parkinsonschen Syndroms mit hohen Dosen Vitamin B₆. [Treatment of the Parkinsonian syndrome with large doses of vitamin B₆.] *Münch. med. Wochenschr.*, 1954, 96, 637-639. [Kölnische Strasse 76, Kassel.]

Twenty patients with Parkinson's disease, 6 of them post-encephalitic cases, were treated with from 600 to 1400 mg. pyridoxine (Benadon) daily, given orally and parenterally. Of the 6 attacked

after encephalitis, 1 was greatly benefited by the treatment, 2 moderately and 3 scarcely at all. Of the 14 with true Parkinson's disease, 9 showed good objective improvement, 3 somewhat less and 2 none. Specimens of handwriting are reproduced in support of the claims. Prospects were better the earlier the treatment was begun.—E. M. Hume.

1207

HAEHNLER, E. and LUDS, H. Der perorale Folsäurestoss-Test und seine differential-diagnostische Bedeutung für die Klinik 1. 2. 3. [The test with a single oral dose of folic acid and its significance in differential diagnosis 1. 2. 3.] *Münch. med. Wochenschr.*, 1954, 96, 477-479; 582-584; 784-785. [Med. Klin., Univ. Cologne.]

1. A method is described of estimating folic acid in the urine by paper chromatography with recognition of folic acid as a black spot in ultraviolet light, and comparison with a standard scale.

The method was used to estimate folic acid in the urine after an oral test dose of 100 mg. Urine was collected after 2, 5, 9, 13 and 24 hr. The peak of excretion in 50 normal subjects occurred after from 5 to 9 hr., and the total amount excreted in the 24 hr. was from 35 to 50 mg. When 50 mg. were given orally, daily for 10 days just before the test dose, the response was greater, up to 80 mg. in the 24 hr.

2. When the test was applied to 8 patients with pernicious anaemia, whether treated or not, the response was much less, ranging from 8.7 to 22.3 mg. in the 24 hr. The test is considered to have diagnostic value.

3. The test was applied in other diseases, and results for a small number of cases are reported. In tuberculosis the result appeared to be normal. In 8 patients with carcinoma in different sites, it was abnormally low, ranging from 10.7 to 24.5 mg. in the 24 hr. The results were indistinguishable from those in pernicious anaemia. A case of Hodgkin's disease and one of myeloblastic anaemia also gave a very low response. Use of the test for differential diagnosis between tuberculosis and carcinoma in certain states of lung infiltration is suggested.—E. M. Hume.

1208

SANSONE, G. Pathomorphosis of acute infantile leukaemia treated with modern therapeutic agents; "meningoleukaemia" and Frölich's obesity. *Ann. paediat.*, 1954, 183, 33-42. [Dept. Paediat., Univ. Genoa.] German and French summaries.

During 3 years, 24 children were treated with aminopterin, alone or with cortisone or adrenocorticotrophic hormone, with apparent complete remission. In the 2 that had the longest remission,

treated with aminopterin or aminopterin and cortisone, severe complications arose going on to blindness, loss of tendon reflexes, loss of muscle strength and obesity. Leucaemic infiltration of the meninges, round the small vessels, and of the pituitary, chiasma, optic tract and olfactory bulb were found. Intrathecal injection of aminopterin reduced the number of cells in the cerebrospinal fluid but produced no clinical improvement.

DARBY, W. J. **Folic acid and citrovorum factor in human nutrition.** *Nat. Vitamin Found., Inc., N.Y., Nutrit. Symposium Ser. No. 7, 1953, 85-99.* [Sch. Med., Vanderbilt Univ., Nashville, Tenn.]

1210

OJI, K., WADA, M. and YOSHIDA, T. **Some aspects of the metabolism of the "citrovorum factor" in humans with liver disease.** *Med. J. Osaka Univ., 1954, 5, 177-185.* [I. Dept. Int. Med., Med. Sch., Univ. Osaka.]

Citrovorum factor, estimated in urine with *Leuconostoc citrovorum* 8081, was much less in patients with liver diseases than in normal adults. The urinary excretion of citrovorum factor in response to administration of folic acid or leucovorin also was low in the patients. The excretion in response to a dose of folic acid was slightly improved if ascorbic acid or vitamin B₁₂ was given simultaneously.

No correlation was established between tests of liver function and excretion of citrovorum factor, but excretion was related to the Hb value in patients with infective hepatitis. Most patients with liver disease showed a tendency to macrocytic anaemia which, it was thought, was related to the disturbance in the metabolism of the citrovorum factor.—A. M. Copping.

1211

PEUCHOT, G. and GAMET, A. **Les anémies gravidocarentielles des pays tropicaux. [Deficiency anaemias of pregnancy in tropical countries.]** *Méd. trop., 1954, 14, 57-64.* [Corps de Santé Colonial.]

The diet of the natives in French Somaliland is based on millet and goat's milk curds. Very little meat is eaten, and anaemia is prevalent, a red cell count as high as 4 million being rare. On such a basis is imposed anaemia in pregnancy, becoming severe about the 6th month or after delivery, with a red cell count below a million, hyperchromia and megaloblastosis. Bilirubin values in the blood are, however, normal, and blood protein values are high with the albumin-globulin ratio normal. Gastric acidity is normal. Thirteen case histories

are given. Treatment is with vitamin B₁₂, 60 µg. daily for 4 or 5 days, then 30 µg. daily for 10 days; folic acid is given at the same time.

This anaemia of pregnancy is thought to be distinct from that seen in Europe or the tropical form of Wills.—E. M. Hume.

1212

ZETTERSTRÖM, R. and FRANZÉN, S. **Megaloblastic anaemia in infancy. Megaloblastic anaemia occurring in an infant of a mother suffering from pernicious anaemia of pregnancy.** *Acta paediat., 1954, 43, 379-385.* [Barnklin., Karolinska Sjukhus, Stockholm.] French, German and Spanish summaries.

The infant was breast fed and developed normally until 2 months old. At 4 months he was admitted to hospital with severe anaemia of megaloblastic type. The mother at this time showed blood and bone marrow pictures typical of healing pernicious anaemia. The child recovered after responding dramatically to a single injection of 15 µg. vitamin B₁₂, and subsequent treatment with folic acid elicited no further response.—D. Duncan.

1213

MOLLIN, D. L. and ROSS, G. I. M. **Vitamin B₁₂ deficiency in the megaloblastic anaemias.** *Proc. Roy. Soc. Med., 1954, 47, 428-431.* [Dept. Pathol., Postgraduate Med. Sch., London.]

It is considered that estimation of vitamin B₁₂ in serum may be of value in investigating megaloblastic anaemia, especially in patients who have little or no haematological evidence of deficiency. Serum vitamin B₁₂ concentrations of about 100 µg. per ml. or less are regarded as suggestive of deficiency. For 126 normal subjects the values ranged from 100 to 900, mean 360, µg. per ml. For 190 patients with pernicious anaemia the value was always below 100, and in most of them below 50. After treatment with vitamin B₁₂ the value rose to within normal limits, and remained high for a time. Among patients with other megaloblastic anaemias, most of those with low initial values responded to treatment with vitamin B₁₂, but of patients with such conditions as idiopathic steatorrhoea or megaloblastic anaemia of pregnancy, a considerable number had normal values while still untreated. Most of them did not respond to treatment with vitamin B₁₂, but responded to treatment with folic or folinic acid. The method is considered convenient for determining the specific deficiency in patients with florid megaloblastic anaemia and, used in conjunction with the haematological response to treatment, may reveal a double deficiency of vitamin B₁₂ and folic acid.—M. B. Richards.

1214

UNGCLAUB, W. G., ROSENTHAL, H. L. and GOLD-SMITH, G. A. **Studies of vitamin B₁₂ in serum and urine following oral and parenteral administration.** *J. Lab. Clin. Med.*, 1954, **43**, 143-156. [Div. Nutrit., Dept. Med., Tulane Univ. Sch. Med., New Orleans, La.]

Vitamin B₁₂ was estimated in blood and urine with *Lactobacillus leichmannii*, and lower values were found in the serum but not in the urine of patients with macrocytic anaemia of different types. Doses of 500, 1000 or 3000 µg. vitamin B₁₂ were given by mouth to 10 normal subjects and of 50, 500, 1000 or 3000 µg. to 8 patients with megaloblastic anaemia. Only with 3000 µg. was there a marked rise in serum values in normal subjects. Patients with pernicious anaemia in relapse showed a slight response to 500 µg. and a good response to 3000 µg. The haemopoietic response was suboptimum with less than 3000 µg. When 10, 25, 50 or 100 µg. were given by intramuscular injection to normal subjects there was a rapid increase in serum and urine values, which was in proportion to the dose. The effects of intramuscular injection of the same amount in 2 patients with pernicious anaemia were like those in normal subjects. There was some relation between values for serum and urine after parenteral administration, but the variation in urine values was very wide. After oral administration there was no apparent relation between the amount in the serum and urine.—A. M. Copping.

1215

GLASS, G. B. J., BOYD, L. J., GELLIN, G. A. and STEPHANSON, L. **Uptake of radioactive vitamin B₁₂ by the liver in humans: test for measurement of intestinal absorption of vitamin B₁₂ and intrinsic factor activity.** *Arch. Biochem. Biophys.*, 1954, **51**, 251-257. [Dept. Med., New York Med. Coll., Flower and Fifth Av. Hosps., New York.]

A new method of testing intestinal absorption of vitamin B₁₂ is based on measurement of the liver uptake of radio-active vitamin B₁₂ containing ⁶⁰Co by means of scintillation counts over the area of skin above the liver and lower abdomen. Counts were made between the sixth and tenth days after ingestion of 1 or 2 µg. radio-active vitamin B₁₂ by 10 normal subjects, 6 patients with pernicious anaemia in remission or relapse and 1 patient with sprue. Little vitamin B₁₂ was absorbed by patients with pernicious anaemia unless normal gastric juice was given, and almost none by patients with sprue whether gastric juice was given or not.—A. M. Copping.

1216

GLASS, G. B. J., BOYD, L. J. and STEPHANSON, L. **Intestinal absorption of vitamin B₁₂ in humans**

as studied by isotope technic. *Proc. Soc. Exp. Biol. Med.*, 1954, **86**, 522-526. [Dept. Med., New York Med. Coll., Flower and Fifth Av. Hosps., New York.]

With the method of measuring radio-activity in the liver described in the preceding Abstract, tests were made on 20 normal subjects after ingestion of 0.5, 1.0, 2.0, 20 or 50 µg. vitamin B₁₂ containing ⁶⁰Co. Absorption was compared with that of the same doses given by intramuscular injection. With intakes of 0.5 or 1.0 µg. about 90 per cent. of the oral dose was absorbed, but as the size of the dose increased, the efficiency of absorption decreased until it was only 3.0 per cent. of the dose of 50 µg. It is suggested, therefore, that, in addition to Castle's intrinsic factor, there may be in the intestinal wall a vitamin B₁₂-acceptor, which would set a partial mucosal block to the absorption of vitamin B₁₂ from the intestine of normal human subjects, and might thus resemble apoferritin in its relation to the absorption of iron.

A. M. Copping.

1218

TURNBULL, A. **Experiences with labelled vitamin B₁₂.** *Proc. Roy. Soc. Med.*, 1954, **47**, 424-426. [Nuffield Dept. Clin. Med., Radcliffe Infirmary, Oxford.]

When 0.5 µg. vitamin B₁₂ labelled with radio-active ⁶⁰Co was given by mouth to 22 patients with pernicious anaemia, from 80 to 95 per cent. of the radio-activity appeared in the faeces, the mean of 39 observations being 88. When the same amount was given to 10 other patients not having pernicious anaemia, only from 20 to 40 per cent. of the radio-activity appeared in the faeces, the mean of 23 observations being 31. When patients with pernicious anaemia were given intrinsic factor with the labelled vitamin B₁₂ the recovery of radio-activity from the faeces was much reduced. It was concluded that the difference between findings in patients with and without pernicious anaemia was due to the failure of the former to secrete intrinsic factor. Patients who had undergone total gastrectomy gave results like those in pernicious anaemia and again, recovery from the faeces was reduced when a source of intrinsic factor was given. The results support the view that in man the stomach is the only gastro-intestinal source of intrinsic factor. Studies were made also on patients with steatorrhoea or megaloblastic anaemia of pregnancy.

N A. and R., January 1955

The technique provides a useful indirect measure for the secretion of intrinsic factor, and should assist in studying the role of vitamin B₁₂ and of intrinsic factor in the megaloblastic anaemias.

M. B. Richards.

1219

BADENOCH, J. The use of labelled vitamin B₁₂ and gastric biopsy in the investigation of anaemia. *Proc. Roy. Soc. Med.*, 1954, **47**, 426-427. [Nuffield Dept. Clin. Med., Radcliffe Infirmary, Oxford.]

Specimens of gastric mucosa were obtained by gastric biopsy tube from 130 patients. The histological changes in the stomach mucosa in anaemia were compared with the amount of intrinsic factor as measured by the absorption of orally given radio-active vitamin B₁₂. In pernicious anaemia there was gross atrophy of the specific glandular tissue of the gastric mucosa, and normal chief or parietal cells could not be seen. It is considered that if such cells are found in any numbers, the diagnosis should be reviewed and a search made for other causes of megaloblastic anaemia. The same technique was applied with varying results to patients with hypochromic anaemia and achlorhydria, and also to 2 patients with megaloblastic anaemia of obscure origin.—M. B. Richards.

1220

HALSTED, J. A., GASSTER, M. and DRENIK, E. J. Absorption of radioactive vitamin B₁₂ after total gastrectomy; relation to macrocytic anaemia and to the site of origin of Castle's intrinsic factor. *New Engl. J. Med.*, 1954, **251**, 161-168. [Wadsworth Gen. Hosp., Veterans Admin. Centre, Los Angeles, Calif.]

In continuation of previous observations (Abst. 1122, Vol. 24) 11 patients who had been subjected to total gastrectomy, of whom 4 were the subjects of the previous study, 11 normal subjects, 7 patients with pernicious anaemia in remission, and 3 patients with idiopathic achlorhydria, were given orally 0.5 µg. vitamin B₁₂ containing radio-active Co. Stools were collected for 5 days afterwards and the content of radio-active vitamin B₁₂ was estimated. All except 2 of the gastrectomy patients had received prophylactic treatment against pernicious anaemia from the time of operation.

The percentage recovered from the faeces, of the amount of radio-active vitamin B₁₂ administered, was from 19 to 57, mean 33, for the normal subjects. For the 3 subjects with idiopathic achlorhydria it was from 20 to 51, mean 35, and for the 7 with pernicious anaemia it was from 80 to 100 unless gastric juice also was given, when the mean value was 38. For the patients subjected to gastrectomy the mean percentage in the faeces was 87 unless gastric juice was given, when it was 20.

Vol. 25, No. 1

The results are taken as clear evidence that the stomach is the only site of secretion of the intrinsic factor. The reason why all patients subjected to total gastrectomy do not develop pernicious anaemia is discussed. Few survive long enough to do so, and many now receive prophylactic treatment.—E. M. Hume.

1221

HEATLEY, N. G., JENNINGS, M. A., FLOREY, H., WATSON, G. M., TURNBULL, A. and WAKISAKA, G. Intrinsic factor in the pyloric and duodenal secretions of the pig. *Lancet*, 1954, **267**, 578-580. [Sir William Dunn Sch. Pathol., Oxford.]

Intrinsic factor activity was tested by oral administration of the preparation at the same time as vitamin B₁₂ labelled with radio-active Co, to patients with pernicious anaemia and measuring the amount of radio-activity which appeared in the faeces. Filtrates of pyloric and duodenal secretions of the pig had activity, but the mucoid residues had little or none. A single test showed activity in a nondialysable residue of duodenal filtrate.—F. C. Aitken.

1222

MASSEY, B. W. and RUBIN, C. E. The stomach in pernicious anaemia: a cytologic study. *Amer. J. Med. Sci.*, 1954, **227**, 481-492. [Frank Billings Med. Clin., Dept. Med., Univ. Chicago, Ill.]

Cells obtained by lavage or abrasion followed by lavage from the stomach of 21 patients with treated pernicious anaemia in remission, and seen in histological studies of parts of the stomach removed by operation from 2 of them, included groups of enlarged cells with abnormal nuclei which might be mistaken for cancer cells and which, it is considered, may be diagnostic of pernicious anaemia. In other tissues of untreated patients with pernicious anaemia, similarly abnormal cells have been reported (Graham and Rheault, *J. Lab. Clin. Med.*, in the press); they return to normal on treatment unlike the gastric cells which remain abnormal after treatment and clinical remission of the disease.—I. Leitch.

1223

SCHELL, R. F., DOCKERTY, M. B. and COMFORT, M. W. Carcinoma of the stomach associated with pernicious anaemia; a clinical and pathologic study. *Surg. Gynecol. Obstet.*, 1954, **98**, 710-720. [Mayo Clin., Rochester, Minn.]

KAIPIAINEN, W. J., NYKOPF, S. and SIURALA, M. The vitamin B₁₂ binding power of gastric juice. *Ann. Med. int. Fenn.*, 1954, **43**, 105-108. [2. Med. Clin., Univ. Helsinki.]

The power of the gastric juice from 50 patients to bind vitamin B₁₂ was studied by adding the juice, sterilised by filtration, to a culture of *Bact. coli* with a known requirement for vitamin B₁₂. No binding power was shown by 32 samples from patients with tapeworm anaemia, gastritis or achlorhydria and from some with apparently normal gastric acidity. One patient whose gastric juice showed power to bind vitamin B₁₂ had pernicious anaemia. No correlation could be demonstrated between power to bind vitamin B₁₂ and gastroscopic or histological findings.

A. M. Copping.

1225

GLAZER, H. S., MUELLER, J. F., JARROLD, T., SAKURAI, K., WILL, J. J. and VILTEE, R. W. The effect of vitamin B₁₂ and folic acid on nucleic acid composition of the bone marrow of patients with megaloblastic anaemia. *J. Lab. Clin. Med.*, 1954, 43, 905-913. [Dept. Int. Med., Coll. Med., Univ. Cincinnati, Ohio.]

Purine and pyrimidine bases were estimated by paper chromatography in aspirated bone marrow from 17 subjects with a normal blood picture, 11 with pernicious anaemia and 1 with sprue. Samples were taken before and after treatment with vitamin B₁₂, folic acid, folic acid or ascorbic acid or combinations of them. In patients with megaloblastic anaemia the concentration of ribonucleic acid and uracil was raised in comparison with that of deoxyribonucleic acid and thymine. The normal ratio between these components was restored after adequate treatment with vitamin B₁₂. Remission of the haematological condition and restoration to normal of the nucleic acid concentration in the bone marrow was obtained in some patients by treatment with folic acid or folic acid combined with ascorbic acid. The findings are discussed with reference to the theory that, in haemopoietic tissues, vitamin B₁₂ and the folic acid and ascorbic acid system produce chemical reactions that favour the formation of thymine and its deoxyribosides, and the depletion of uracil and its nucleotides.—A. M. Copping.

1226

GORDIN, R. Prothrombin in cryptogenic pernicious anaemia and pernicious tapeworm anaemia and its response to treatment. *Acta med. scand.*, 1954, 149, 1-18. [A. Med. Clin., Maria Hosp., Univ. Helsinki.]

Of 47 patients with cryptogenic pernicious anaemia and 42 with pernicious anaemia due to tapeworm infestation, 57.4 and 54.8 per cent., respectively, had prothrombin values below 80 per cent. of normal. In subjects with a Hb value below 60 per cent. or a red cell count below 2.5 million, the incidence of low prothrombin values was, respectively, 78 and 75 per cent. in the group

with cryptogenic anaemia and 54 and 55 per cent. in the group with tapeworm anaemia; the lowest values were usually found in patients with severe anaemia. In 71 patients with secondary anaemia, however, and in 36 with post-haemorrhagic anaemia of severity equal to that of the patients with pernicious anaemia, prothrombin values were seldom low. In those in whom proconvertin was estimated, the values for it followed the prothrombin values. Vitamin B₁₂ was effective for treatment of the anaemia, but had no effect or only a transitory one on the prothrombin value; after treatment with crude liver extract, however, the prothrombin values rose to normal levels and remained high. In both types of patient an extract of tapeworm given by intramuscular injection produced a positive but transitory effect on the prothrombin value. In other cases a worm cure produced a positive and persistent effect. Vitamin K had no effect on the prothrombin value. From the results it is concluded that the low value for prothrombin was due to transient liver damage, which is less likely to be present in the more acute cases of tapeworm infestation.—L. Wills.

1227

BEARD, M. F., PITNEY, W. R. and SANNEMAN, E. H. Serum concentrations of vitamin B₁₂ in patients suffering from leukemia. *Blood, J. Hematol.*, 1954, 9, 789-794. [Sect. Haematol., Dept. Med., Sch. Med., Univ. Louisville, Ky.] Spanish summary.

Vitamin B₁₂ was estimated in blood serum with *Euglena gracilis* according to the technique of Ross (Abst. 386, Vol. 23). The ranges and mean values in $\mu\mu\text{g. per ml.}$ were for 22 normal subjects from 86 to 460 and 184, for 18 patients with chronic lymphatic leukaemia from 40 to 540 and 209, for 12 with chronic myeloid leukaemia from 540 to 6500 and 2732, and for 7 with acute leukaemia from 216 to 1000 and 599. In the patients with chronic myeloid leukaemia there was a correlation between the total white cell count and the vitamin B₁₂ concentration in the serum, and the serum had increased capacity to bind vitamin B₁₂. Electrophoresis of the sera showed that vitamin B₁₂ was bound in the α -globulin fraction. The possibility that the high vitamin B₁₂ concentration in serum from chronic myeloid leukaemia might be the result of decreased erythroid activity is discussed. The vitamin B₁₂ content of the serum in chronic lymphatic leukaemia appeared to be normal; the values in acute leukaemia were variable but above normal.—A. M. Copping.

1228

BEARD, M. F., PITNEY, W. R., SANNEMAN, E. H., SAKOL, M. J. and MOOREHEAD, H. H. Serum

N.A. and R., January 1955

concentrations of vitamin B₁₂ in acute leukemia. *Ann. Int. Med.*, 1954, 41, 323-327. [Louisville, Ky.]

Vitamin B₁₂ estimated with *Euglena gracilis* in serum from 20 patients with acute leukaemia ranged from 116 to 9200 $\mu\text{g.}$ per ml. In the 11 patients with acute lymphocytic leukaemia the values fell within the normal range; in the 3 with monocytic leukaemia the values were only moderately increased; in the 6 with acute myelocytic leukaemia very high values were obtained. There was no correlation between white cell count and serum concentration of vitamin B₁₂. No successful treatment was achieved for the patients with acute myelocytic leukaemia, so it was not possible to assess the effect of treatment on the value for vitamin B₁₂ in the serum.—A. M. Copping.

1229

DAUR, W. Vitamin B₁₂ in der Therapie der Poliomyelitis. [Vitamin B₁₂ in treatment of poliomyelitis.] *Münch. med. Wochenschr.*, 1954, 96, 729-730. [Inn. Abt., Städt. Krankenhaus, Ravensburg.]

Injection of 3 doses of 30 $\mu\text{g.}$ vitamin B₁₂ as Rubivitan Bayer given to 34 patients with acute poliomyelitis prevented the onset of paralysis in 26 treated in the early stages, and allowed rapid general improvement in 8 with severe paresis or paralysis. The treatment appeared to have a beneficial effect on muscle tone and on neuro-muscular signs. In one patient a disturbed sleep rhythm was restored to normal shortly after injection of vitamin B₁₂. The possible mode of action of the vitamin is discussed with reference to its role in cell metabolism.—A. M. Copping.

SAUER, H. and DÜSSLER, A. Über das Krankheitsbild der diabetischen Polyneuritis und seine Behandlung mit Vitamin B₁₂. [Signs and symptoms of diabetic polyneuritis and its treatment with vitamin B₁₂.] *Deutsch. med. Wochenschr.*, 1954, 79, 1046-1048. [I. Med. Klin., Univ. Hamburg, Eppendorf.]

After a brief review of the literature a report is given of the results of treatment of 18 diabetic patients with polyneuritis. After a period in which saline solution only was injected, the patients received from 30 to 60 $\mu\text{g.}$ vitamin B₁₂ by intramuscular injection daily for from 1 to 2 weeks; 15 patients showed improvement but in 3 the condition was unchanged, in 2 even after

higher doses of the vitamin. Paraesthesia, hyperaesthesia, hyperalgesia and burning of the feet all decreased but absent reflexes, reduced sensitivity to touch and pain, and abnormal vegetative functioning were not affected. The possible mode of action of vitamin B₁₂ in the condition is discussed.—L. Wills.

1232

SHUMAN, C. R. and GILPIN, S. F. Diabetic neuropathy: controlled therapeutic trials. *Amer. J. Med. Sci.*, 1954, 227, 612-617. [Hosp., Temple Univ., Philadelphia, Pa.]

Control of their diabetes by adequate treatment, including a high-protein diet, produced improvement or complete disappearance of nerve symptoms in 12 of 37 patients studied. The remaining 25, while continuing on the same diet, were given alone or in various combinations vitamin B₁₂ in daily intramuscular doses up to 1000 $\mu\text{g.}$, vitamin B complex, extract of pregnant mammalian liver or adenosine triphosphate with vitamin B₁ or pantothenic acid in adequate doses. Subjective improvement occurred in some of the patients, but in none was there any change in the objective signs.—L. Wills.

LARCOMB, J. W., PERRY, C. S. and PETERMAN, R. A. Dietary supplementation of vitamin B₁₂ in prepuberty school-age children. 1. Growth studies. *J. Pediat.*, 1954, 45, 70-74. [Dept. Paediat., Coll. Med., Ohio State Univ., Columbus.]

From 500 children initially selected in schools for deaf and blind children, 132 were observed for a whole school year. Sixty of them received 20 $\mu\text{g.}$ vitamin B₁₂ daily and 72 had an inactive tablet. The treatment had no effect on the height or weight of normal children but caused a significant increase in the weight of children who were underweight at the beginning of the study. In children who were overweight vitamin B₁₂ appeared to accelerate growth in height.—A. M. Copping.

JOLLIFFE, N., FUNARO, R., FRONTALI, G., MAGGIONI, G., CORBO, S. and LANCIANO, G. Vitamin B₁₂ as a growth factor in Italian children on diets low in animal protein. *Nat. Vitamin Found., Inc.*, N.Y., *Nutrit. Symposium Ser.* No. 7, 1953, 119-132. [Paediat. Clin., Rome.]

The effect of adding vitamin B₁₂ to a diet providing from 20 to 30 per cent. less energy, and from 15 to 40 per cent. less protein, than the allowances recommended by the National Research Council (U.S.) was studied in children at an orphanage in Rome and at an elementary school in a depressed

area at Gaeta. In all, 351 children aged from 6 to 12 years were treated for 7 months. Significant increase in weight gain was associated with administration of vitamin B₁₂, but no difference in gain of height was seen between treated and untreated children. The observations are being continued.—A. M. Copping.

CHOW, B. F. The interrelationship between vitamin B₁₂, steroids and protein metabolism. *Nat. Vitamin Found., Inc., N.Y., Nutrit. Symposium Ser. No. 8, 1954, 14-25.* [Sch. Hyg. Pub. Health, Johns Hopkins Univ., Baltimore, Md.]

The paper is partly a review and partly a preliminary report of results in the press. It sums up the present knowledge of the part played by vitamin B₁₂ in the metabolism of protein, fat and carbohydrate, and suggests a probable relation of the vitamin to adrenal function.

Observations on diabetic subjects showed that those with retinitis retained less of an injected dose of vitamin B₁₂ than those without. The effect was possibly related to adrenal abnormality, since patients with diabetic retinopathy excreted more free cortisone than normal subjects. The excretion of steroid substances was investigated in response to testosterone and in relation to retention of injected vitamin B₁₂.—A. M. Copping.

KAYE, R., CAUGHEY, R. H. and McCRODY, W. W. (with MURPHY, D. V.) Effects of vitamin B₁₂ and aureomycin on nitrogen retention in infants. *Pediatrics, 1954, 13, 462-475.* [Child Hosp., Philadelphia, Pa.] Spanish summary.

Nitrogen balance studies were made with 3 infants given a liquid diet containing 3.6 per cent. protein, and 3 having only 0.4 per cent. protein. After a preliminary period of from 4 to 6 days, from 30 to 300 µg. vitamin B₁₂ were given for 5 or 6 days, and 2 subjects subsequently received both vitamin B₁₂ and aureomycin. There was no clear evidence that addition of vitamin B₁₂ to a diet of high or low protein content altered nitrogen metabolism. In the infants having low-protein diets nitrogen retention increased slightly when vitamin B₁₂ was given but decreased in those with a high-protein intake. Neither vitamin B₁₂

nor aureomycin had any significant effect on weight gain. Some stimulation of appetite was seen in 2 infants. All subjects remained in positive balance for Na, K and Cl throughout the tests. The diet with 0.4 per cent. protein, which provided about 0.1 g. per kg. bodyweight daily from cow's milk, was apparently close to the minimum nitrogen intake for maintaining equilibrium in infants in the conditions of the study.

GORTEN, M. K. and BRADLEY, J. E. The treatment of nutritional anemia in infancy and childhood with oral iron and ascorbic acid. *J. Pediat., 1954, 45, 1-12.* [Sch. Med., Univ. Maryland, Baltimore.]

Two groups of 10 children aged between 8 and 29 months were given a mixture of ferric ammonium citrate, folic acid and vitamin B₁₂; the second received, in addition, amounts of between 500 and 750 mg. ascorbic acid daily. In every child the initial Hb value was below 7 g. per 100 ml. blood. Full haematological investigations were made, with statistical evaluation of the results.

For the groups in order, the average lengths of treatment were 21 and 17 days, and the mean initial Hb values 5.1 and 4.2 g. per 100 ml. blood. The average times taken for the means to reach 11 g. were 29 and 21 days, and mean increases in reticulocyte counts were 11.0 and 23.6 per cent.

It is concluded that with 20 mg. Fe per kg. bodyweight daily the rate of improvement can be bettered if the dose is supplemented with between 500 and 800 [as stated] mg. ascorbic acid daily, and that treatment lasting between 14 and 17 days should suffice to produce good recovery.

VORONIN, P. F. Zavisimost' katalaznoi aktivnosti krovi ot obespechnosti organizma vitaminom C. [Dependence of the catalase activity of blood on the supply of vitamin C to the organism.] *Biokhimiya, 1953, 18, 279-283.*

Observations were made of the relation in human blood between ascorbic acid and catalase activity. A study was made also of the seasonal

N.A. and R., January 1955

variation in the catalase content of blood, and of changes in the catalase activity of the blood of adults transferred from the southern and northern regions of the U.S.S.R. to the Polar regions. A definite and not an accidental link was shown to exist between the two values. The effect of ascorbic acid on catalase depended on the original ascorbic acid state of the organism. Blood catalase activity was subject to seasonal variations. There was a definite change in the catalase activity of the blood of people being acclimatised from their native regions to Polar conditions. People from the south had originally a higher value for ascorbic acid in the blood and correspondingly a higher catalase activity. After a certain time in the Polar regions the ascorbic acid content of the blood of the southern people decreased while that of the northern people increased, and there was a corresponding decrease and increase in catalase activity. After 6 months in the Polar regions, ascorbic acid and catalase activity increased again in the blood of the people from the south.

LEBLANC, J., STEWART, M., MARIER, G. and WHILLANS, M. G. Studies on acclimatization and on the effect of ascorbic acid in men exposed to cold. *Canad. J. Biochem. Physiol.* 1954, 32, 407-427. [Defence Res. Med. Labs., Toronto, Ont.]

Twelve airmen were confined in a room maintained at $59^{\circ} \pm 1^{\circ}$ F. for 11 days after an initial period at $79^{\circ} \pm 1^{\circ}$ F. A survival diet of jelly candy was given supplying 550 Cal. daily. Six received 525 mg., and six 25 mg., ascorbic acid daily. A daily record was made of weight, B.M.R., rectal and skin temperature, erythrocyte, leucocyte and eosinophil counts, water consumption, and volume and composition of urine.

The group which received the larger amount of ascorbic acid had a higher skin temperature, a higher eosinophil count and less discomfort from the cold than the others. The mean B.M.R. measured in bed varied widely in the low-vitamin C group and fell in the high-vitamin C group to a level significantly below that in the low-vitamin C group. The small excretion of 17-ketosteroids in both groups was referred to the reduced activity of the adrenal glands on a protein-free diet. At the end of the experiment pain in the feet also was less in the high-vitamin C group. After 5 days in the cold both groups showed a significant increase in skin temperature though the body temperature was unaffected. Diuresis was greatly reduced. Leucocyte and erythrocyte values rose at first but returned to normal and remained steady; during the last days of the experiment the subjects felt warmer and shivered less. The facts suggested definite acclimatisation to cold.

Vol. 25, No. 1

A similar experiment was performed with the same two supplements of ascorbic acid and a normal diet supplying 3400 Cal. daily. Oxygen consumption rose in the cold. There was an average daily weight gain of 80 g. compared with a loss of 340 g. in the first experiment. On the assumption that loss of 1 g. weight represents 6.6 Cal., with a diet of 3400 Cal. value and a weight gain of 80 g. daily, the true requirement of the men was calculated to be 2870 Cal., and from a loss of weight of 340 g. daily with a diet giving only 550 Cal. the true requirement would be 2800 Cal. Further, if the oxygen consumption rose by 15 per cent. in the cold, the extra heat produced to compensate for a drop in external temperature from 80° to 60° F. was estimated to be 400 Cal. daily; the normal requirement of men in sedentary occupation at 80° F. would then be about 2400 Cal. No significant difference was found between subjects given much or little ascorbic acid. Signs of acclimatisation to cold such as were observed in the first experiment were not seen, but an increase in excretion of 17-ketosteroids suggested that there was some adaptation of the adrenal cortex.—A. Hepburn.

ROSENBERGER, P. Prophylaxe und Frühbehandlung von Grippe und Erkältungskrankheiten in einem Industrieunternehmen während der letzten Jahre. [Prevention and early treatment of influenza and colds in a factory in recent years.] *Deutsch. med. Wochenschr.*, 1954, 79, 1230-1231. [Steubenstrasse 7, Düsseldorf, Reisholz.]

In the 3 weeks reckoned critical for risk of an influenza epidemic, an industrial concern employing 3000 people distributed to them between 50,000 and 60,000 tablets of Aspicorbin (Bayer) containing aspirin 0.1 g., phenacetin 0.1 g., ascorbic acid 0.05 g. and quinine hydrochloride 0.01 g. The workers were instructed to take 1 tablet three times daily, or 2 three times daily if they felt symptoms of infection. Figures obtained from the *Krankenkasse* of the works showed a percentage sickness for the workers in January to March 1951 of from 5.5 to 6.8, compared with from 10 to 13 in neighbouring works, and in 1952 of from 4.4 to 5.5 compared with from 7 to 9. In 1953 the difference was less, other works also having given prophylactic treatment. The duration of illness too was diminished.—E. M. Hume.

1244

CASS, L. J., FREDERIK, W. S. and COHEN, J. D. Chronic disease and vitamin C. *Geriatrics*, 1954, 9, 375-380. [Dept. Hyg., Med. Sch., Harvard Univ.]

In the Long Island hospital for chronic disease,

Boston, a study was made for 5 months of 140 elderly patients, including 39 with arthritis, 25 with diabetes and 12 with multiple sclerosis. The average daily vitamin C intake from the usual hospital diet was 59 mg. and from the diabetic diet 109 mg. The effect of orange juice, ascorbic acid and aspirin on blood vitamin C was studied with 3 similar groups of the patients. Vitamin C was estimated in whole blood, plasma and the white cell layer [method not stated]. Results for eosinophil count, blood sedimentation rate and cholesterol content also are tabulated for the 3 groups during the different treatments. Mean values for those with diabetes and arthritis, and others are tabulated also.

Orange juice and ascorbic acid raised the blood vitamin C value. Aspirin did not reduce it. Large amounts of vitamin C promoted wellbeing in patients with arthritis and multiple sclerosis.

BAUR, H. and STAUB, H. Hepatitistherapie mit Ascorbinsäureinfusionen. [Treatment of hepatitis with transfusions of ascorbic acid.] *Schweiz. med. Wochenschr.*, 1954, 84, 595-597. [Med. Klin., Univ. Basle.] English summary.

Ascorbic acid is considered to have a specific action against viruses. Patients with infective hepatitis were kept in bed with a certain basic treatment. Eleven of them were given for 5 days a daily intravenous transfusion of 1 litre physiological saline containing 10 g. ascorbic acid. The results were compared with those for groups of patients, 195 in all, given 7 other treatments in vogue from 1947 to 1953. The serum bilirubin value fell, and patients were able to leave hospital, more quickly with the ascorbic acid treatment than with any other. Promotion of diuresis and tests for liver function gave very favourable results.—E. M. Hume.

1248

GSELL, O. and KALT, F. Hochdosierte Ascorbinsäurebehandlung der epidemischen Polio-

myelitis. [Treatment of epidemic poliomyelitis with large amounts of ascorbic acid.] *Schweiz. med. Wochenschr.*, 1954, 84, 661-666. [Med. Poliklin., Univ. Basle.]

In view of statements in the literature that ascorbic acid could inactivate the poliomyelitis virus *in vitro* the effect of daily doses of from 0.02 to 0.5 g. per kg. bodyweight was investigated in 125 patients. The treatment was commenced by the third day of illness in 43, by the seventh day in 63, and later in 19, but there was no significant effect on paralysis or mortality rate in comparison with the rates during the previous 15 years. The recovery from paralysis was not influenced by treatment with daily doses of from 5 to 25 g. ascorbic acid as Redoxon.—A. M. Copping.

Other Vitamins

1250

PLUM, P., DAM, H., DYGGVE, H. and LARSEN, E. H. Administration of vitamin K ante partum. Prophylaxis against haemorrhagic disease of the newborn. *Danish Med. Bull.*, 1954, 1, 21-23. [Dept. Paediat., Rigshosp. Univ., Copenhagen.]

From a short review of the literature, it is concluded that vitamin K should be given as a routine to all mothers just before or during labour. The dosage recommended is 40 mg. of the dicalcium salt of 2-methyl-1:4-naphthohydroquinone diphosphoric ester (Synkavit) given orally from 48 to 4 hr. before delivery, or 10 mg. of the tetrasodium salt of the same compound given intravenously up to 30 min. before delivery. If the mother has received no treatment, the infant should be given from 5 to 10 mg. by intramuscular injection immediately after birth.—E. M. Hume.

1251

PIGEAUD, H., NELKEN, S. and BOHE, H. Taux de prothrombine chez le nouveau-né après injection intra-veineuse chez la mère de vitamine K synthétique au cours de l'accouchement. [Prothrombin value in the newborn infant after intravenous injection of synthetic vitamin K into the mother during labour.] *Presse méd.*, 1954, 62, 1123. [Lyons.]

Prothrombin values in 35 infants whose mothers had been given injections of vitamin K during labour ranged from 39 to 105 per cent. of normal. Average values for infants grouped according to

N.A. and R., January 1955

the time between injection and birth were 70, 73 and 74, which approximated closely to the accepted average of 75 per cent. for newborn infants of untreated mothers.—F. C. Aitken.

DENTAL DISEASES

1252

NEVIN, R. B. The diet and mastication; their effects on diffusion and on the inception of dental caries. Progress Printing Co. Ltd., Dunedin, N.Z., 1954, pp. 43.

Measurements were made of the diffusion rates of lactic and hydrochloric acids from between glass rods spaced at 0.08 and 0.15 mm. and immersed in buffer solutions and saliva. Movement of glass slides and of closely adapted areas of impression compound simulated mastication and obstruction of the spaces between rods by measured amounts of filter paper simulated the presence of food debris. The experiments indicated that the properties of food alone or mixed with saliva should be evaluated in terms of permeability, adhesiveness, buffer capacity, acidity, and "packing quality". Sugar content and sugar-forming potentialities are also important, but changes in physical properties may be more important than variations in sugar content. Sugar solutions are much less dangerous than sugar incorporated in sticky foods. Inception and development of caries may result from steep gradients in concentrations of sugar and acids in narrow spaces rather than from high concentrations of sugar. In fissures and interproximal areas, caries may be a relatively continuous but fluctuating process; caries of exposed surfaces is intermittent and requires greater sugar concentrations. Local variations in caries incidence are controlled largely by the amount of food debris retained. This is determined by the shape, size and position of the teeth and degree of muscular activity.

R. B. Nevin (New Zealand).

1253

NEVIN, R. B. Experimental observations on the diet and oral hygiene in relation to dental caries. Progress Printing Co. Ltd., Dunedin, N.Z., 1954, pp. 15.

The effects of a mixture of biscuit and saliva on the rate of diffusion of lactic acid from between closely spaced glass rods support the conclusion that changes in the physical properties of food may have a greater effect on caries incidence than have variations in sugar content. Tooth-brushing experiments conducted similarly show that only when there is no restriction to interchange of fluids can the toothbrush effectively free the narrow spaces from sugar and acids. These experiments, and others made with a lower partial denture equipped with removable crowns of natural teeth in correct approximal relation, showed that

sticky foodstuffs are not easily dislodged from narrow spaces even by very vigorous brushing. Insufficient or inefficient brushing tended to force such material further into the space. Impacted or adherent debris may result in prolonged retention of sugar and acids in narrow spaces even when some tooth-brushing is undertaken. Spacing of teeth is important in food retention: slight spacing may have a greater locking effect than tight contact. Beyond a certain critical degree of spacing clearance of debris becomes efficient but further evaluation of toothbrush techniques and their effectiveness is necessary with special reference to different age groups. Suggested intra-oral methods include dentures with removable and adjustable crowns of natural teeth, and the use of 2-part inlays in which the interproximal contact area forms a wedged slide, movable mesiodistally in the main cemented part, and locked by a screw or small wedge.

R. B. Nevin (New Zealand).

1254

STACK, M. V. The independence of caries experience and salivary tryptophane content. *J. Dent. Res.*, 1954, 33, 316-320. [Dept. Dent. Med., Guy's Hosp., London.]

Rate of flow was measured and tryptophan content estimated in samples of saliva obtained from 34 school children and 56 students, who were taken as normal subjects, and from 55 outpatients at a dental hospital. For the outpatients additional information was available on DMF rates and on susceptibility to caries as measured by lactobacillus counts, buffer capacity measurements and modified Fosdick tests (Dewar, *Thesis, London Univ.*, 1953) made on their saliva.

The mean value for tryptophan for the outpatients, 22 $\mu\text{g.}$ per litre, did not differ from the means for the control groups, each 23 $\mu\text{g.}$ per litre. When the data for all subjects were arranged in class intervals of 5 $\mu\text{g.}$ their frequency distribution was abnormal with 39 and 38 subjects, respectively, in the 16 to 20 and 26 to 30 $\mu\text{g.}$ groups and only 23 subjects in the central, 21 to 25 $\mu\text{g.}$, group.

In the group of patients no correlation was found to exist between DMF rates and salivary tryptophan content.—D. Harvey.

1255

SUHER, T., DICKSON, J. P. and HADJIMARKOS, D. M. Caries experience among institutionalized children in the Pacific Northwest. *J. Dent. Res.*, 1954, 33, 552-557. [Dept. Paedodont., Dent. Sch., Univ. Oregon, Portland.]

The incidence of caries was studied in 327 children of between 6 and 14 years of age who were resident in 4 institutions for 9 months in the year. Two institutions were for deaf and one for blind children; the fourth took normal Indian children.

DMF rates for teeth and surfaces are tabulated for each year of age; they ranged from 2.06 and 3.50, respectively, at 6 to 14-95 and 27.30 at 14 years. Comparison is made with findings by Klein and Palmer with schoolchildren in "On the Epidemiology of Dental Caries", 1941, Univ. Pennsylvania Press and with the earlier data of the Oregon workers (Absts. 996, Vol. 20 and 2396, Vol. 24) for children in an institution and in public schools.

The high incidence of caries found in the present investigation does not support the view that children living under institution conditions are affected by caries to a less extent than is the general school population.—D. Harvey.

1256

PIERANGELI, R. E. and DE NARANJO, C. G. El porcentaje de alimentos protectores sobre el valor calorico total de la dieta y la incidencia de caries en los adultos. [Percentage from protective foods of total energy value of the diet and incidence of caries in adults.] *Rev. Assoc. argent. Dietologia*, 1953, 11, 139-142.

For this study the total quantities of food consumed by 50 students during one week were measured and the percentages of total energy derived from protective foods were calculated and correlated with the incidence of caries. The highest incidence of caries occurred when the proportion from protective foods was less than 40 per cent. of the total; the incidence was smaller when the percentage was over 50, and still less when over 60. The action of the protective foods was modified somewhat by the proportion of carbohydrates in the diet. The inhibiting effect on the incidence of caries increased when carbohydrates provided less than 50 per cent. of the total energy value, and diminished when the percentage was over 50. With equal intake of carbohydrates the incidence of caries was less with increased intake of protective foods.—M. B. Richards.

1257

PORTER, K. O. and WOODS, E. Dental caries prevalence in children 15 and 16 years of age in three Idaho communities. *J. Dent. Res.*, 1954, 33, 542-551. [Dept. Home Econ. Res., Univ. Idaho, Moscow.]

A study was made of 215 children in 3 Idaho communities with different amounts of F in their drinking waters; Coeur d'Alene, none; Boise 0.5; Nampa 1.5 p.p.m. DMF rates were recorded by both clinical and X-ray examination. The incidence of caries was noticeably greater in Coeur d'Alene than in the two other towns, its rate of 16.7 DMF teeth being higher than any recorded from elsewhere for comparable children. Comparison of Boise with Nampa children showed that the rate in Nampa was 26 per cent. below that in

Boise, but the difference was not statistically significant.

Data on rainfall and knowledge of type of vegetation linked high rainfall and leaching of soil carrying forest vegetation at Coeur d'Alene with lower Ca, Mg, Fe and F levels in the drinking water than were found at Boise and Nampa with low rainfall, little leaching and desert shrub vegetation. Further studies are needed to establish the relationship between caries susceptibility and the mineral constituents of soil and drinking water.

X-ray examinations are concluded to be unnecessary for school survey work.—D. Harvey.

1258

SYRIST, A. and KARLSEN, K. A five-year report on the effect of topical applications of sodium fluoride on dental caries experience. *Brit. Dent. J.*, 1954, 97, 1-6. [Dept. Paedodont., State Dent. Sch., Malmö.]

Work with 116 volunteer children was started in 1947 and, over 2 years and at intervals of 3 to 4 months, they were given 7 applications of a 2 per cent. solution of sodium fluoride to their incisors, canines and premolars in one quadrant. Untreated quadrants in the same children were controls. Ninety-one children returned for subsequent study at yearly intervals for 3 years. All examinations were made by one observer and decayed and filled surfaces, DF rates, were recorded.

The percentages of DF surfaces in treated and untreated quadrants, respectively, were, before treatment 5.38, 5.44; after 2 years' treatment 9.10, 12.48; in the first post-treatment year 14.26, 17.69; in the second 17.04, 21.69; and in the third 22.81, 27.34. The total number of non-carious surfaces at risk was the same, 1705, in both quadrants at the beginning of the experiment; at the end of the treatment period there had appeared 67 new DF surfaces in the treated and 127 in the untreated group; over the 3 post-treatment years corresponding numbers were 247 and 268. The difference between the mean value for new DF surfaces per child for control and treated quadrants, i.e., the average reduction in DF surfaces per child resulting from treatment, was 0.65 in the treatment period; it was significant. In the 3-year period after treatment it was 0.23 and was not significant. For the whole 5 years it was 0.9 DF surface per child and was highly significant.

The data are thought not to be sufficiently complete for an assessment to be made of the value, as a routine public health measure, of topical applications of a solution of NaF to the teeth.—D. Harvey.

1259

CLARKE, J. H. C. The value of fluoridation of domestic water supplies in prevention of dental
N.A. and R., January 1955

caries and dental sepsis. *Med. Officer*, 1954, 92, 39-43. [Kesteven, Lincs.]

Samples of water from the Kesteven district were found to have F contents ranging from 0 to 4 p.p.m. Schools were selected in widely separated villages where the amounts were 0, 0.2, 0.7 and 2.5 p.p.m. and in them records were made by a single observer of the DMF rates for those pupils who had resided in the district for the whole of their lives.

For each of 9 age groups the average tended to vary inversely with the F content of the water; for all age groups the average rates in ascending order of F content were 8.14, 8.00, 6.18 and 3.15. Corresponding data for average number of teeth missing per child were 1.57, 1.31, 1.61 and 0.44 and for percentage of children with relatively sound dentition, i.e., 0 to 2 DMF, 3, 5, 17 and 42 per cent. At the schools with the highest F content in drinking water cavities were smallest and caries appeared to be least active.

The subject is discussed and the officially recommended rate of fluoridation, 1.2 to 1.5 p.p.m., is, from the Kesteven evidence, concluded to be a safe one.—D. Harvey.

1260

NEILL, A. H. Aspectos técnicos de la fluoruración. [Technical aspects of adding fluoride to water.] *Bol. Ofic. sanit. panamer.*, 1954, 36, 181-189. [Serv. Sanid. Pub. U.S.A.] English summary.

1261

McCAULEY, H. B. and McCLURE, F. J. Effect of fluoride in drinking water on the osseous development of the hand and wrist in children. *Pub. Health Rep., Washington*, 1954, 69, 671-683.

Three groups of children, aged 7 to 14 years, 591 at Amarillo and 690 at Lubbock in Texas and 769 at Cumberland in Maryland, were examined. The Texas children had had drinking water with about 4 p.p.m. F and, at Amarillo, sometimes as much as 6.2 p.p.m., those in Maryland water with a low level of F, 0.12 p.p.m. at the time of the study. Ossification ratios as described by Carter (*J. Educat. Psychol.*, 1926, 17, 237) and skeletal age by the Todd standard were measured. The data are tabulated according to chronological age, the F content of the water and the degree of mottling of enamel seen at Amarillo and Lubbock and are compared with those reported by Flory (*Abst. 3602*, Vol. 7) for normal U.S. children.

No evidence was obtained to indicate that a level of F between 3.5 and 6.2 p.p.m. in drinking water has any adverse effect on the growth of carpal bones or causes any alteration in the difference in rate of skeletal maturation known to exist between boys and girls. The conclusion is that

controlled fluoridation of public water supplies at the rate of about 1 p.p.m. F is safe as a measure for the reduction of tooth decay.—D. Harvey.

KREPKOGORSKII, L. N. K probleme flyuoroz. [Contribution to the problem of fluorosis.] *Gigiena Sanit.*, 1953, No. 11, 7-10. [Kazakh. Inst. Epidemiol.]

A survey was made of the fluoride content of drinking water and of fluorosis in schoolchildren in a number of localities in certain regions of Kazakhstan. The fluoride contents of the water samples varied from 1 to 3 mg. per litre and in one case reached a value between 7 and 10 mg. per litre. Children with a mild degree of fluorosis of the teeth had a lower percentage incidence of caries than those with no evidence of fluorosis, but caries was most common in the group with the most severe degree of fluorosis. Populations drinking the same water throughout sometimes showed a higher incidence of dental fluorosis than those using more than one water supply, although these latter might at times be consuming water with a very high fluoride content.—D. W. Taylor.

1263

HAMAMOTO, E., FUJIWARA, H., KIMOTO, H., FURUTANI, A., YOSHIMATSU, M., ODA, N., OHARA, T. and ANDO, H. On bone changes observed in residents of high fluorine zone. *Proc. Japan Acad.*, 1954, 30, 53-60. [Dept. Paediat., Med. Sch., Univ. Okayama.]

In 1952-53 examination was made of 247 inhabitants of Odani village in Okayama prefecture. In 25, signs and symptoms referable to the joints were found, and X-ray examination showed the bone changes to be extensive and characteristic of fluorine poisoning. In 10 of the 25, estimation of 17-ketosteroids in the urine gave a mean value of 6.9 mg. in the 24 hr. for men and 4.5 for women; the corresponding values for normal subjects were 12.5 and 9.6. The cases all occurred on farms using water from wells containing from 6 to 13 p.p.m. F. Water from other neighbouring wells, with which fluorosis was not associated, contained from 0 to 2 p.p.m.—E. M. Hume.

THERAPEUTIC AND PREVENTIVE DIETETICS

GENERAL

1266

POLLACK, H. Amino acids and protein in therapy. *Nat. Vitamin Found., Inc., N.Y., Nutrit. Symposium Ser. No. 8*, 1954, 91-103. [Mount Sinai Hosp., New York.]

Changes in N metabolism in disease and after injury are discussed and conditions affecting the patient's protein requirement are outlined. It is important to assure an adequate intake of energy as well as of protein. It is pointed out that the allowances recommended by the U.S. National Research Council for normal persons are not intended to meet the requirements created by pathological states or the demands during nutritional rehabilitation. Yet many hospital therapeutic diets do not supply these recommended allowances. In support of this contention the nutritive value of New York hospital diets are quoted.

The use of preparations of milk solids in high-protein diets and of protein hydrolysates or amino-acid mixtures in intravenous feeds is briefly described.—F. C. Aitken.

1267

SCHLEGEL, J. U. A new approach to the treatment of electrolyte disturbances in shock and severe stress. *Surgery*, 1954, 35, 449-459. [Sch. Med. Dent., Univ. Rochester, N.Y.]

In the treatment of sodium retention in shock and severe stress a distinction is drawn between physiological and pathological retention, and an indirect method of establishing the type of retention is described. The method requires the measurement of fluctuations of urine pH, for which a suitable pH meter is described and illustrated.

F. C. Aitken.

1268

O'BRIEN, J. R. Is liver a "tonic"? A short study of injecting placebos. *Brit. Med. J.*, 1954, ii, 136-137.

Four groups of non-anaemic patients, 86 in all, were given injections totalling 227 of a liver extract, vitamin B₁₂ or normal saline. From their replies to questions put in standardised form on their general wellbeing, energy, appetite and sleeping it is concluded that they were unable to distinguish between the injections. The suggestibility of the patient was important and women were more suggestible than men.—D. Harvey.

DIABETES

1270

HARTMANN, A. F. (Sr.), WOHLTMANN, H. J. and HARTMANN, A. F. (Jr.) Dietary fructose in children with diabetes mellitus. *J. Pediat.*, 1954, 45, 27-50. [Dept. Paediat., Sch. Med., Washington Univ., St. Louis, Mo.]

The diets of 5 children were varied so that the sugar supplying 25 per cent. of the total energy was sometimes fructose, sometimes sucrose and at other times glucose. In 4 of the children insulin requirement remained constant despite the changes in diet. In the fifth child a seeming insulin-sparing effect of fructose was attributed to spontaneous improvement of tolerance.—F. C. Aitken.

1271

LESTRADET, H. and SEYNAEVE, A. Le problème du régime chez l'enfant diabétique. Effet d'une augmentation importante de l'apport hydrocarboné sur la glycosurie et les besoins insuliniques. [The dietary problem of the diabetic child. The effect of a considerable increase in carbohydrate on glycosuria and insulin requirement.] *Presse méd.*, 1954, 62, 707-709. [Inst. Nat. Hyg., Paris.]

A holiday settlement for diabetic children provided the opportunity to study, in 8 children, the effect of an abrupt change of diet on the 24 hr. excretion of sugar and on insulin requirements. The children had been on a restricted diet containing only 80 to 150 g. carbohydrate but after 5 days in the settlement the older ones were permitted to take diets containing 350 to 400 g. carbohydrate, and the younger 250 to 300 g. Increased loss of sugar such as might have been expected if the processes regulating it were really dependent on a definite "tolerance" of the organism for carbohydrates did not occur. The findings are thought to favour treatment of diabetic children with insulin only provided it is rigorously controlled, and the daily dose is based on analyses of urine made every 2 or 3 days.

M. B. Richards.

1272

LOOS, M. Studies in the utilization of pentoses in diabetics. *Acta med. scand.*, 1954, 148, 425-431. [2. Med. Clin., Univ. Hamburg, Eppendorf.]

A study of 9 normal and 63 diabetic subjects showed that there was no difference between diabetics and healthy individuals in the utilisation of xylose or in its influence on carbohydrate metabolism. In all cases there was good absorption with no disturbance, provided a single dose

N.A. and R., January 1955

did not exceed 40 g. and the total daily intake 80 g. In no case was pentose excreted by the intestine. Urinary pentose excretion was on the average 15 per cent. in the healthy subjects and 13.5 per cent. in the diabetic. In no diabetic patient was there a deterioration of condition. Glucose was never excreted in increased amount after ingestion of xylose. When patients were given 40 g. glucose and 40 g. xylose on consecutive days nearly all showed, on the xylose day, less glucosuria and a lower excretion of β -hydroxybutyric acid. This favourable influence of xylose on the excretion of glucose and ketone may be attributable to a stimulating effect on intermediary metabolism, and the good effect of a vegetable diet in diabetes may be explained by its pentose content.—M. B. Richards.

GASTRO-INTESTINAL CONDITIONS

1280

FRIEDRICH, L. and TIBOR, F. Le traitement dit "par placebo" de l'ulcère et les épreuves d'activité. [Treatment by placebo of ulcer and tests of activity.] *Acta gastro-enterol. belg.*, 1954, 17, 521-538. [Hôp. Koranyi, Budapest.] Dutch, English, German and Spanish summaries.

Placebo treatment was given to 188 patients, 135 men and 53 women with gastric or duodenal ulcer. In hospital they received injections of physiological saline and on discharge tablets containing a small quantity of NaHCO_3 .

In 92 patients subjective symptoms disappeared in a week, in 33 after 2 weeks and in 13 after 3 weeks; in 50 the symptoms continued. X-ray examination after a month showed that 30 gastric and 58 duodenal ulcers had disappeared and 27 gastric ulcers were smaller. The long-term results were somewhat less good; nevertheless, 25 per cent. of the patients remained symptom-free after a year.—D. Duncan.

RUFFIN, J. M., CARTER, D. D., JOHNSTON, D. H. and BAYLIN, G. J. "Wheat-free" diet in the treatment of sprue. *New Engl. J. Med.*, 1954, 250, 281-282. [Dept. Med., Sch. Med., Duke Univ., Durham, N.C.]

A patient with long-standing sprue in severe relapse was treated with a wheat-free diet and calcium. There was immediate and dramatic clinical improvement. After 3 months the patient had gained 43 lb. X-ray studies showed that the pattern of the small intestine had become regular. Biochemical tests showed that blood protein and serum Ca were normal and that there was improvement in absorption of vitamin A and glucose. In an addendum, remissions are reported in 2 other patients who were receiving the wheat-free diet.—F. C. Aitken.

1284

MACLEAN, L. D., PERRY, J. F., KELLY, W. D., MOSSEY, D. G., MANNICK, A. and WANGENSTEEN, O. H. Nutrition following subtotal gastrectomy of four types (Billroth I and II, segmental and tubular resections). *Surgery*, 1954, 35, 705-718. [Dept. Surg., Med. Sch., Univ. Minnesota.]

The causes of weight loss after subtotal gastrectomy were studied in a group of 35 patients, of whom 32 had lost weight. In 8 patients there was an abnormally high faecal excretion of fat. In only 3 could excessive fat loss be attributed to pancreatic insufficiency as judged by the secretion test and in only 1 of these patients was there an excessive excretion of N in faeces, characteristic of pancreatic insufficiency. Patients who lost weight claimed to be eating less food since operation.

It is suggested that treatment might more profitably be directed towards increasing energy intake than towards improving fat absorption.

F. C. Aitken.

1285

KELLY, W. D., MACLEAN, L. D., PERRY, J. F. and WANGENSTEEN, O. H. A study of patients following total and near-total gastrectomy. *Surgery*, 1954, 35, 964-982. [Dept. Surg., Med. Sch., Univ. Minnesota, Minneapolis.]

Twenty-six patients were studied 2 months to 8 years after operation. Data on weight, eating habits and gastro-intestinal signs, faecal fat and N excretion, pancreatic function, blood picture, iron tolerance, X-ray studies and oesophagitis are tabulated and discussed. In general there was loss of weight, which seemed to be due to reduced food intake. Faecal fat was increased but, on the average, by an amount insufficient to account for the loss of weight. Pancreatic function was not impaired. Megaloblastic anaemia occurred frequently in patients who survived for a long time. Impaired iron absorption and hypochromic microcytic anaemia also occurred.

A high-calorie, high-protein, high-fat diet with small and frequent meals is recommended. Anaemias respond to the appropriate treatment.

F. C. Aitken.

1286

BEAL, J. M., BRIGGS, J. D. and LONGMIRE, W. P. Use of jejunal segment to replace the stomach following total gastrectomy. *Amer. J. Surg.*, 1954, 88, 194-197 (with discussion 197-199). [Surg. Serv., Wadsworth Hosp., Veterans Admin. Centre, Los Angeles, Calif.]

The use of a jejunal implant appears to enhance the assimilation of food by the patient after total gastrectomy. The majority of the 29 patients in

this series were able to take a normal diet in multiple small feedings and the weights of most were satisfactory. The anaemia which frequently develops can usually be controlled by parenteral administration of vitamin B₁₂ and liver extract.

M. B. Richards.

1287

BARON, A. Body weight after gastrectomy. *Brit. Med. J.*, 1954, ii, 69-73. [St. George's Hosp., London, S.W.1.]

Records of bodyweight were available for 285 patients who had undergone subtotal gastrectomy, and were compared with British insurance companies' standards. Before operation more than 75 per cent. of the subjects were underweight. The group showing post-operation failure to gain weight included a high proportion of those whose pre-operation loss of weight had been greatest, 30 to 40 per cent. of standard. Loss of weight after operation was most pronounced in those whose weight before operation had been much above standard.

In 12 patients who were fed by drip with a mixture high in energy and protein from the third morning after operation loss of weight in the early post-operation period was prevented. Such feeding, especially of patients weighing less than 80 per cent. of standard, is worthy of consideration.

D. Harvey.

1288

WIESNER, H. Über die alimentäre enterogene Kollapsneigung magenresezierter Patienten. [Tendency to collapse after a meal in patients after gastrectomy.] *Ztschr. ges. inn. Med.*, 1954, 9, 252-254. [Chirurg. Klin., Städt. Krankenhaus Altstadt, Magdeburg.]

Hurry, consumption of carbohydrate and simultaneous intake of fluid are predisposing causes of collapse. To lie down gives relief. The same effect can be produced in normal subjects by giving 100 g. glucose in 250 ml. water through a stomach tube.

The condition was investigated in 7 women and 34 men who had been subjected to gastrectomy from 2½ weeks to 2 years previously. Blood pressure, pulse rate and fasting blood sugar were measured before and at frequent intervals after administration of glucose as just described. Four of the patients whose operation was most recent suffered complete circulatory collapse. Thirty-eight had a rise of pulse rate, and 14 a rise of blood pressure, but 11 had a slight fall of blood pressure. Twenty-two reported unpleasant sensations. On the whole, the more remote the operation, the less the upset. The condition occurred while the blood sugar was rising and could not be ascribed to hypoglycaemia.—E. M. Hume.

ORTIZ DE LANDÁZURI, E., MORREALE DE CASTRO, G., ESCOBAR DEL REY, F. and MORA LARA, J. R. Valor clínico de la iodemia en las alteraciones del tiroides. [Clinical value of blood iodine in thyroid changes.]

MORREALE DE CASTRO, G., ORTIZ DE LANDÁZURI, E., MORA, J. R., ESCOBAR DEL REY, F. and ARANZANA, A. La iodemia en el bocio endémico. [Blood iodine in endemic goitre.] *Rev. clín. española*, 1954, **52**, 236-247; 247-253. [Clin. Méd., Univ. Granada.] English, German and French summaries.

The results of laboratory tests were compared with the clinical findings in 50 patients with different forms of goitre. In hyperthyroidism the estimation of protein-bound I in the blood proved valuable, since it indicated the functional state with greater sensitivity than did the B.M.R. or blood cholesterol value, although frequently all 3 tests agreed. In hypothyroidism, on the other hand, B.M.R. and blood cholesterol appeared to be more sensitive. In such cases there were frequently differences not only between clinical and laboratory findings, but also among the laboratory finding themselves. In following the results of treatment, whether surgical or with thyroxine or thiouracil, estimation of organic I proved most useful, since its variations were greater and were evident at an earlier stage than were those of the B.M.R. or blood cholesterol. The most interesting application of the method is probably in relation to thyroidectomy, since it indicates the most suitable post-operative treatment and prevents the occurrence of thyrotoxicosis, common in such patients and accompanied, paradoxically, by a fall in the organic I.

A statistical study was made in a region of endemic goitre in Granada, where the incidence of goitre was over 50 per cent. In general the goitres were small, with normal clinical function, although there were cases of hypo- and hyperthyroid syndromes. Etiologically most importance was attributed to I deficiency, since very small amounts, 0.23 to 0.25 µg. per litre, were found in the waters analysed. The values for organic I in the serum were mostly near the upper normal limit, sometimes above it. This might be interpreted as evidence of thyroid hyperactivity of pituitary origin, or of a disturbance in the biosynthesis of the hormone, whereby I compounds with no hormonal activity would enter the blood-

stream and the organic I level would not be a measure of the amount of thyroxine and triiodothyronine circulating in the blood. In the region studied a prophylactic campaign with iodised salt has been introduced.—M. B. Richards.

Brit. J. Radiol., 1954, **27**, 381-386. [Nuffield Dept. Clin. Med., Oxford.]

The metabolism of Fe is briefly reviewed.

Two tests are described in which measured amounts of Fe labelled with ^{59}Fe are given either by mouth in an ordinary hospital mixture or intravenously in a sample of the patient's serum. The tests were made on patients in whom treatment of hypochromic anaemia with Fe by mouth had been unsuccessful. Of 18 such patients 8 were found to have idiopathic steatorrhoea.

The tests were valuable for distinguishing patients in whom there was a true failure of absorption of Fe from others in whom conditions such as intolerance of treatment, excessive loss of Fe by haemorrhage or inability to utilise Fe after absorption might account for the lack of response to treatment and for whom case histories might be lacking or misleading.—D. Harvey.

1299

WEAVER, J. A. and NEILL, D. W. **Amino-aciduria in pernicious anaemia and subacute combined degeneration of the cord.** *Lancet*, 1954, **266**, 1212-1213. [Royal Victoria Hosp., Belfast.]

The urine amino-acids were estimated by paper partition chromatography. In 5 patients with untreated pernicious anaemia and in one with subacute combined degeneration of the cord with normal blood and bone marrow findings there was abnormally high excretion of taurine associated with varying degrees of excess of lysine, cystine and leucine; treatment with vitamin B_{12} caused the pattern of excretion to return towards normal. In patients with other types of anaemia of similar degree the amino-acid pattern was found to be normal.—L. Wills.

OTHER CONDITIONS

1300

TOMPKINS, W. T. and WIEHL, D. G. **The significance of nutrition and nutritional deficiencies in pregnancy.** *Nat. Vitamin Found., Inc., N.Y., Nutrit. Symposium Ser. No. 7*, 1953, 133-155. [Nutrit. Res. Clin., Pennsylvania Hosp. (Philadelphia Lying-in Hosp.), Philadelphia.]

Data are presented graphically to show that the woman who is underweight at the onset of pregnancy has the greatest likelihood of both premature labour and toxæmia. The woman who is obese is also more likely to develop toxæmia than is the woman of normal weight; her tendency to do so is, however, not as great as that of the woman who is underweight. Low Hb values are related to the occurrence of premature labour and low serum proteins to that of toxæmia. These and other data emphasise the importance of nutrition in pregnancy.—F. C. Aitken.

1301

FERGUSON, A. W. and MCGOWAN, G. K. **Idiopathic hypercalcaemia of infants. Low-calcium treatment.** *Lancet*, 1954, **266**, 1272-1274. [Child's Hosp., Bristol.]

The basis of the low-calcium diet is cow's milk treated by passage through cation exchange resin in a simple apparatus which is described in detail, or artificial human milk prepared from low-ash casein. Four infants with hypercalcaemia were given one of the 4 treatments, resin-treated cow's milk, resin-treated human milk, artificial human milk followed by resin-treated cow's milk or artificial human milk. In each there was improvement of wellbeing, rapid gain of weight and a fall of serum Ca. Although recovery is usually spontaneous, the results seem to justify the use of such diets.

[Clinical results of the treatment with a liver hydrolysate of chronic hepatitis and cirrhosis of the liver.]** *Gastroenterologia*, 1954, **81**, 300-318. [Med. Klin., Freie Univ., Berlin.] English and French summaries.

Treatment was controlled for up to 3½ years by laparoscopy and liver biopsy. Results were good in some patients.—I. Leitch.

1305

SJÖVALL, B. **Fettsot och dess behandling. [Obesity and its treatment.]** *Nord. Med.*, 1954, **51**, 871-874. [Lasarettet, Karlskoga, Sweden.] English summary.

Reasons are given for regarding obesity as a disease, or a complication rendering many other diseases more serious. There has been no survey of its incidence in Sweden. Among 2300 hospital patients 24 per cent. of the men and 45 per cent. of the women were overweight. The majority of such patients respond satisfactorily to restricted diet providing 800 to 1200 Cal. daily, but, out of 84 so treated in hospital, 12 (14 per cent.) responded

N.A. and R., January 1955

very slowly or did not lose weight. Controlled tests should be made of Pennington's theory that the obese cannot oxidise pyruvic acid and that pyruvic acid interferes with the oxidation of fat, which implies a therapeutic diet of lean meat and fat (see Abst. 2440, Vol. 24).—I. Leitch.

1306

SCHREINER, B. and GOLLMANN, T. Ein neuer Weg zur Behandlung der Fettsucht. [A new method of treating obesity.] *Wien. klin. Wochenschr.*, 1954, 66, 213-214. [Med. Klin., Univ. Graz.]

In this summary of a lecture a brief account is given of the author's method of rapid weight reduction by initial treatment with ion exchange substances. After a period of great fluid loss thus induced, it was possible to give the patients a low-calorie diet with unrestricted fluid intake and to achieve satisfactory loss of fatty tissue. It is stated that the use of the ion exchange method gives much greater comfort to the obese subject during weight loss, and that it does not disturb the electrolyte balance in the blood or cause changes in the electrocardiogram.—A. M. Copping.

1307

HARVEY, H. I. and SIMMONS, W. D. Weight reduction: a study of the group method: report of progress. *Amer. J. Med. Sci.*, 1954, 227, 521-525. [Herrick Mem. Hosp., Berkeley, Calif.]

More evidence was obtained in favour of the group method of weight reduction (Abst. 1227, Vol. 24) but the permanency of the results seems doubtful. Of 188 women questioned, over one-third associated the onset of obesity with pregnancy, illness or operation. Eating between meals was a common habit, and bread a favourite food. W. M. Deans.

SEIFERT, W. H. Poliomyelitis and the relation of diet to its treatment. *J. Amer. Dietetic Assoc.*, 1954, 30, 671-673. [Northwestern Univ. Med. Sch., Chicago, Ill.]

Bulbar poliomyelitis is the form requiring most careful diet treatment, since swallowing is difficult or impossible. Feeding is at first by vein, then oral feeding is introduced in 4 stages: (1) tube feeding, (2) liquid diet, (3) soft diet, (4) more solid diet. When the patient is able successfully to swallow all foods given in stage 4 he is allowed the high-calorie, high-protein, high-vitamin diet prescribed in spinal poliomyelitis.—F. C. Aitken.

DEPEYSTER, F. A. and GILCHRIST, R. K. Clinical response of spontaneous hypoglycemia to dietary and drug therapy. *J. Amer. Med. Assoc.*, 1954, 155, 884-889. [Dept. Surg., Presbyterian Hosp., Chicago, Ill.]

The treatment of choice in spontaneous hypoglycaemia is excision of the islet cell adenoma, but management before operation is important. In one of 3 cases reported hypoglycaemic attacks were prevented by a dietary regimen of 3 meals daily with between-meal feeds so that food was taken every 3 hr. Dietary management failed in the second patient because the regimen was not strictly followed and in the third because between-meal feeds were inadequate. Alloxan administration failed to control the hypoglycaemia of the second patient but corticotropin, at least 25 mg. daily, was effective in the management of the third. In this patient 50 mg. cortisone alone or 25 mg. cortisone with 10 mg. corticotropin was ineffective.—F. C. Aitken.

ZORN. Konstitution durch Ernährung und Haltung. [Constitution through diet and management.] *Ztschr. Tierzücht. Züchtungsbiol.*, 1954, 63, 87-99. [Inst. Konstitutionsforsch., Forschungsanst. Landwirtschaft., Völkeneinrode, Grub.]

Constitution is defined as "the capacity of the body to react to external stimuli" or, more simply, "the resistance of the individual to harmful influences". In modern views it is determined partly by inheritance and partly by environment.

For instance, it has been estimated that longevity is only 30 per cent. inherited and 70 per cent. the result of environment. The discussion is concerned chiefly with the general virtues of balanced diet and "open-air" housing, e.g., of pigs in moveable huts and cattle in open stalls.—I. Leitch.

CRASEMANN, E. Einige Probleme der Diätetik bei der Fütterung auf betriebseigener Grundlage. [Some problems of rationing when home-produced feedingstuffs are used.] *Fortpflanzung, Suchthyg. Haustierbesamung*, 1954, 4, 1-8. [Inst. Haustierernährung, Tech. Hochschule, Zürich.]

Home produced feedingstuffs should be understood to include not only those grown on the farm but residues from dairy, cheese factory and kitchen, milling offal and industrial residues such as yeast, sugar beet pulp and fruit waste. The proper use of home-grown feeds requires that rations shall be of such water content that the requisite nutrients can be taken daily. This is important at least for ruminants; probably much less for pigs and poultry. The amount of indigestible residue (ballast) must not be too great; colour and texture, smell, taste and stimulant effects must be acceptable; there should be neither poison nor dirt in the feedingstuffs and the temperature should be suitable. Each of these points is discussed with reference to ruminant, pig, rabbit, and sometimes poultry.

The use of home-produced feeds must be carefully planned also to supply the correct amount of protein. There is a danger of deficiency disease which may appear in seasons of bad weather or when the necessary fertilisers are not applied. The defects of particular plants and classes of plants must be remembered, e.g., the high oxalic acid content of beet leaves and the goitrogenic effect of *Brassicaceae*.—I. Leitch.

GALLUP, W. D., WHITEHAIR, C. K. and BELL, M. C. Utilization of urea and protein nitrogen by ruminants fed high-molasses and sugar rations. *J. Animal Sci.*, 1954, 13, 594-600. [Dept. Agric. Chem. Res., Oklahoma Agric. Exp. Stat., Stillwater.]

Six Hereford steers were used in two 20-day N balance trials. A basal ration of 53.7 per cent. prairie hay, 44.8 per cent. cane molasses and 1.5 per cent. of a mixture of salt and bonemeal was given to 2 of the steers; 2 others were given urea as a supplement to the basal ration and 2 soya bean oilmeal. The urea supplied 54 per cent of the total N and the soya bean oilmeal replaced the molasses so that the total N content equalled that of the urea ration.

Steers on the basal ration lost weight and failed to maintain positive N balance. Those on the supplemented rations maintained weight and retained from 13 to 17 per cent. of the N intake. The apparent digestibility of the N was higher in the urea than in the soya bean ration. The results indicated a more efficient utilisation of soya bean N than urea N. Supplements of soya bean oilmeal and urea increased the digestibility of the organic matter and crude fibre of the basal ration.

The utilisation of N in rations containing either sucrose, glucose, or lactose was estimated in balance trials with 12 wether lambs. The experimental rations were identical except for the kind of sugar used. Nutrient digestibility and N utilisation were similar in all 3 rations.

ALDER, F. E. Some effects of fertilizers on the output of leys with particular reference to extension of the grazing season. *J. Brit. Grassland Soc.*, 1954, 9, 29-33. [Grassland Res. Stat., Hurley, Berks.]

Several manurial experiments on pasture made at Hurley, Berkshire are surveyed. Cocksfoot and alfalfa are of value for grazing during the summer dry period and it is suggested that when they are sown in alternate rows, nitrogenous fertiliser could be used more economically if applied only to the grass drills, obviating suppression of the legume. For winter grazing the yield and winter-green condition of cocksfoot were improved by high levels of N application. N also increased the crude protein content of herbage through the year, but unless potash was deficient, superphosphate had little effect beyond small increases in P content. Ten different seeds mixtures on 36 acres of downland, liberally manured, have maintained the equivalent of one mature bullock on $\frac{1}{2}$ acres on grazing alone for 9 to 10 months of the year. Hay and silage from the same area were given for the rest of the year. Liveweight increase was 318 and 335 lb. per acre in 2 successive years.—J. L. Corbett.

ESAT-KADASTER, I. Orta anadolu hayvan Yemleri. [Crop feedingstuffs of Middle Anatolia.] *Arb. Yüksek Ziraat Enst. Ankara*, No. 85, 1940, Turkish text, pp. 227; German text pp. 207; + 56 (Pictures and Tables).

This thesis presents the results of pioneer work

done in 1935 on the feedingstuffs in use in Middle Anatolia. It is prefaced by a brief description of the region. Rainfall is low, 200 to 350 mm., mostly in winter and spring, but water shortage is not acute. Straw is the main feed. When the supply runs out in dry years the peasants collect *Astragalus* spp., mainly *A. tragacantha* (tragacanth), from the hills in autumn or winter. The whole plant, roots and all, is cut up and pounded, work which can be done indoors. They also collect thorny plants, the best of which is kangal (*Cirsium*, creeping thistle), for threshing. Certain oilseeds grow wild or are cultivated.

Samples of feeds purchased or collected in different parts of the region were analysed by German official methods (numbers in brackets): meadow hay (7), lucerne hay (8), *Cirsium* (3), *Astragalus tragacantha* (3), wheat straw (11), rye straw (1), barley straw (5), oat straw (2), barley (5), oats (3), melenir (*Cephalaria syriaca*) (3), safflower seed (1), safflower cake (1), linseed cake (2), and izgin (*Eruca sativa* (cappodocia)) cake (2). From 1 to 3 samples of all but straws of rye, barley and oats were used for digestibility trials with 2 or 4 Karaman wethers. The results for proximate composition of the natural feed and its dry matter, digestibility coefficients, and digestible nutrients in the dry matter are tabulated in detail and discussed with reference to the literature, if any. Some of the findings are briefly as follows [values quoted in the summary are not all consistent with the main text]. Meadow hay was low in digestible protein, but rich in energy. Lucerne hay was exceptionally good, probably owing to the sunny climate. The straw substitute *Cirsium* (digestible protein 4.25 per cent., starch value per 100 kg. 20) was much better than straw, provided the animals would eat it; cattle will, but sheep do not always readily do so. The same is true of tragacanth. According to these experiments tragacanth had a lower starch value than *Cyrtium*, but this is contrary to the views of the peasants. Wheat straw, that most used, was good only as ballast. *Cephalaria* seeds had digestible protein 13.94 per cent. and starch value 92.24. Safflower seeds were bitter and unpalatable; safflower cake was eaten, but the values were inferior to those in the literature. For linseed cake the results were similar to those reported elsewhere. *Eruca sativa* cake was rich in nutrients but was not readily eaten. It is concluded that the best prospects for the future lay in the encouragement of the cultivation of lucerne and, for concentrates, of oilseeds, either those already grown or those growing wild.—W. M. Deans.

BROUWER, E. and BRANDSMA, S. Over de minerale bestanddelen en hun onderlinge verhoudingen

N.A. and R., January 1955

in verschillende voedermiddelen en rantsoenen. [The mineral constituents and their ratios in various feedingstuffs and rations.] *Med. Landbouwhoges.* Wageningen (Nederland), 1953, 53, No. 3, 31-73.

Tables of composition of feedingstuffs compiled by Wolff (1880) and Mach and Herrmann (1934) and analyses from the Centraal Veevoederbureau of hay in 1931, 1932 and 1933 are used to prepare diagrams showing the characteristic groupings of inorganic constituents in feeds of different types. Then typical winter rations for a dairy cow are similarly treated.

When average values for individual feeds are used in the computation of composition of the rations, the dispersion of composition of the rations is small and all approach theoretical requirements. The dispersion so computed is less than that of many single feedingstuffs. The chief differences derive from the type of farming for which the rations were planned. Rations for mixed farms where green fodder of sugar beet, fodder beet or turnips is much used may have a base excess greater than that of pasture where tetany occurs. Rations on purely pastoral farms had low earth-alkalinity ($\text{Ca} + \text{Mg} - \text{P}$). In general winter rations supply more Mg than does grass, and the transition from stall-feeding to pasture would, on most farms, imply a relative fall in Mg intake. The Na supply is also relatively low on pasture alone and that of K is high: the ratios are better on mixed farms.—I. Leitch.

1335

LEROY, A. M. Mesure de la quantité d'herbe ingérée par un ruminant en liberté au pâturage au moyen de la comparaison des compositions chimiques du fourrage ingéré et des matières fécales excrétées. [Measuring the quantity of herbage consumed by ruminants at pasture by comparison of the chemical composition of the pasture consumed and of the faecal matter excreted.] *Ann. Zootech.*, 1952, 1, No. 4, 43-48. [Inst. Nat. Agronom., Paris.]

From published results the author calculates that the quantity of faecal N per 100 g. organic matter ingested, n , varies with the percentage of N in the faecal organic matter, N , so that when $N = 1.5$, $n = 0.54$ and when $N = 5.0$, $n = 0.81$. There is also a negative correlation between the crude fibre content of the organic matter of grass and its coefficient of digestibility. A relation is shown between the faecal crude fibre per 100 g. organic matter ingested and the coefficient of digestibility of the organic matter. By collection of faeces in bags from animals at pasture it is possible to know the weight of faecal organic matter excreted in 24 hr. and to estimate the N and crude fibre contents. From the coefficients

tabulated the coefficient of digestibility of the organic matter ingested may be calculated from the formula $(N - n)/N$.—D. Duncan.

1336

KATSHIO, Y. [Studies on the determination of productive value of feeds in poultry. 1. Relation of the intake of indigestible organic matter to the energy expenditure by poultry. 2. Relation of the indigestible organic matter content in ration to maintenance, growth, egg-production, or fattening. 3. Digestion trials of Japanese popular feeds with poultry.] *Bull. Nat. Inst. Agric. Sci., Japan* [G], 1954, 8, 169-292. In Japanese: English summary.

1. The net productive energy of feeds for poultry was estimated by respiration calorimeter. Rations were fed at sub-maintenance, maintenance, and above-maintenance levels to find the energy used in digestion, by (a) the gizzard (muscular stomach), and (b) the remainder of the alimentary tract (peristalsis). Powdered feeds were given at varying levels of intake to estimate the energy consumption of peristalsis, and whole grain versus powdered grain was given to estimate the energy consumption of the muscular stomach.

The total digestible nutrients (T.D.N.) contents of diets for maintenance, growth and fattening were then corrected for the work of digestion, these corrections (expressed as T.D.N.) being related to the content of indigestible organic matter and/or dry matter, in the ration.

2. Groups of 20 to 30 hens were fed for a period of approximately 1 month on 10 different mixtures of feed containing varying amounts of indigestible organic matter. The highest utilisation of nutrients for maintenance, growth, egg production or fattening was obtained when the daily intake of indigestible organic matter was between 20 to 25 g.

3. Forty kinds of popular Japanese feeds were tested in digestibility trials with poultry. The digestibility of nutrients was estimated by chemical analysis of the mixed excreta (urine plus faeces), not by separate collection of urine and faeces by means of an artificial anus, or by the use of tracer methods. (From English summaries.)

1337

NOLAND, J. E. and MORRISON, S. H. The digestibility of honeysuckle (*Lonicera japonica*) for yearling dairy bulls. *J. Dairy Sci.*, 1954, 37, 173-175. [Dairy Dept., Univ. Georgia, Athens.]

A digestibility trial was made with a pair of identical twin Jersey bulls. During each of the 10-day trial periods the terminal shoots of honeysuckle were given as the sole roughage. The chemical composition was estimated. The average digestion coefficients were: fat 22.1, crude protein

66-8, crude fibre 42-6, N-free extractives 69-5. The average total digestible nutrient content of the fresh material was 23 per cent.—J. N. Aitken.

1338

MARRERO, J. L. Composicion de la "Asphodelus microcarpus", Viv, y de la "Ampelodesmos tenax", Lk. y su posible utilizacion como alimento animal. [Composition of *Asphodelus microcarpus*, Viv, and of *Ampelodesmos tenax*, Lk., and their possible use to feed animals.] *Bol. Inst. nac. Invest. agronom., Madrid*, 1954, 14, 75-82. English summary.

The samples of *Asphodelus microcarpus* and *Ampelodesmos tenax* came from Majorca, where the plants are abundant and are called *Aubó* or *Porrasa* and *Carrita*. Because of their high fibre content both are considered more valuable for ruminants than for pigs. Both are useful bulky fodders, of somewhat higher energy value and digestible protein content than cereal straw.

D. Duncan.

1339

ŠMALCERJ, I. Tikva, bundeva (*Cucurbita pepo* L. var. *mellopepo*, Heyek) kao krma za stoku. [Pumpkin (*Cucurbita pepo*, L., var. *mellopepo*, Heyek) as livestock feed.] *Veterinaria*, 1952, 673-686. English summary.

The pumpkin is an important succulent fruit for livestock in Yugoslavia. Three different kinds were investigated. Pumpkins are usually an intercrop of maize. The yield of pumpkin fruits per hectare was from 84 to 110 metric cwt. The green plant gives a yield of 11-4 to 24-11 metric cwt. per hectare and is also used for feeding livestock. The weights of single fruits were from 1-73 to 3-25 kg. The quantity of pumpkin seeds is considerable and they are important for oil production.

S. Pribičević (Yugoslavia).

1340

CAMBURN, O. M. and JONES, C. H. Comparison of sun-cured and barn-cured hay from the same field. *Vermont Agric. Exp. Stat. Bull.* No. 574, November 1953, pp. 19. [Burlington, Vt.]

The report covers 6 hay seasons, 1944 to 1949, with timothy, alfalfa, red clover and mixed hay (bromegrass, timothy and clover) to test the effect of sun- and barn-curing on the composition, nutritive value and losses after 3 months' storage. Barn-curing was by blowing unheated air through the hay.

Percentage losses in sun-cured and barn-cured hays were: dry matter 6-08, 4-11; crude protein 4-99, 7-02; crude fibre 2-52, 2-88; N-free extract 9-21, 4-28; ether extract 11-60, 10-08. Digestibility trials with cows were made on each sample of hay and digestion coefficients and total digestible nutrients are recorded. From 34 di-

gestibility trials the total digestible nutrients of sun-cured and barn-cured hays were found to be 48-47 and 48-78, respectively. Retentions of Ca and P during storage were similar under both methods of curing. Sun-cured hays showed a loss of water-soluble carbohydrates. Yields of cured hay per acre were 1-57 tons for sun-curing and 1-77 tons for barn-curing. Retention of carotene in the hay was much higher with barn-curing than with sun-curing.—J. S. Thomson.

1341

MOXON, A. L., GASTLER, G., STAPLES, G. E. and JORDAN, R. M. Grass hay at its best as shown by chemical analysis and feeding value. *S. Dakota Agric. Exp. Stat. Bull.* No. 405, January 1951, pp. 23.

Investigations over 8 years were made in different areas of South Dakota to determine the changes in chemical composition of grasses during the growing season and the relation between time of cutting and yield. Digestibility trials were also made to assess the relationship of composition to feeding value. The grasses used were mostly western wheat grass and blue grama.

Data on composition at different stages of growth from shooting to ripening showed the usual decrease in protein and increase in fibre, with a fall in P and an increase in Mn content. Yields of dry matter per acre over a 2-year period were 400 lb. higher for early than for late cutting and yields of protein 50 lb. per acre higher. Hay cut in July and left in the windrow for winter feed showed little change during that time in protein or P content, but hay left standing in the field showed large decreases; both types showed considerable loss of carotene, the standing crop losing all its carotene while the windrow crop retained a quarter of its original content. Digestibility trials with steers and lambs on prairie hay cut early, medium or late showed a progressive fall in digestibility coefficients for all nutrients with time of cutting. It was calculated that early-cut hay supplied over 5 times as much digestible protein for steers as late-cut hay. Feeding trials with calves generally showed the superiority of early- and medium-cut hays over late-cut. Hay cut at the early to medium stage and stored for 3 years was still superior to late-cut hay used in the year it was harvested.—J. S. Thomson.

1342

DODSWORTH, T. L. Further studies on the fattening value of grass silage and on the effect of the dry-matter percentage of the diet on dry-matter intake in ruminants. *J. Agric. Sci.*, 1954, 44, 383-393. [N. Scotland Coll. Agric.] Four groups of bullocks were fattened on silage only, roots and oat straw in the morning and silage

N.A. and R., January 1955

in the evening and vice versa, and on a mixture of roots, oat straw, oats and hay. Silage alone produced the greater rate of fattening and had the highest efficiency of dry matter (DM) conversion. The feeding of roots in the morning and silage at night caused a 10 per cent. increase in DM consumption and a greater gain in weight than when the order of feeding was reversed. The starch equivalents (SE) of roots and silage were higher when they were given together.

In another experiment sheep fed on silage of 19.46 per cent. DM from the bottom of the silage pit consumed 16.7 per cent. more DM and 19.8 per cent. more SE than sheep fed on the same silage watered to 15.85 per cent. DM. Digestibility of the DM was about the same in both groups. After 39 days both groups were given silage from the top layer containing 15.77 per cent. DM. The digestibility of the DM on changing from 19.46 to 15.77 fell by about 10 per cent. but returned to the original value after 10 days.

The SE of the silage from the bottom layer of the pit calculated from the results of digestibility trials on sheep and from the cattle feeding trials was 65.88 and 66.15 per cent. Losses of DM and of crude protein from 25 silos each averaged about 40 per cent.—A. Hepburn.

1343

PAVLOV, I. Kormovaya tzennost' ozimoi rhi v kachestve zelenoi podkornki. [The feeding value of winter rye as a green fodder.] *Sovet. Agronom.*, 1953, No. 5, 93-94. [All-Union Sci. Res. Inst. Agric. Animals Nutrit.]

A mixture of meadow grasses (red clover, timothy, *Festuca pratensis*, *Bromus inermis* and *Dactylus glomerata*) and a mixture of red clover and *Festuca pratensis* produced a higher yield of greenstuff and absolute dry matter than winter rye. The dry matter in the grasses was 39.8 per cent. higher than in the winter rye. The nutritive value of the grasses was also considerably higher.

LIESCHER, W. Beitrag zur Frage der Keimfutterbereitung. [Production of germinated fodder.] *Bodenkultur*, 1953, 7, 254-267.

Because inflated claims of the superior value of fodder from grains grown in nutrient solutions without soil are again being made, the results of

hitherto unpublished experiments made with oats, barley and maize at the *Landwirtschaftlich-chemische Bundesversuchsanstalt* in Vienna in 1935 are now reported.

Comparison of the germinated fodder with the original grain on a dry basis showed that the former was lower in organic matter by from 20 to 40 per cent. and in true protein and N-free extract, higher in crude protein, amides, crude fibre and minerals. The greater weight of the germinated fodder was almost all due to water; small quantities of minerals were taken up from the nutrient solution, but there was no synthesis of protein.

Trials with two 5-year-old wethers given barley or germinated barley along with hay gave the following digestibility coefficients: organic matter 86.6, 76.9; crude protein 85.2, 75.1; true protein 84.2, 66.1; crude fat 87.0, 76.2; N-free extract 90.8, 83.1; crude fibre 45.4, 43.4. The losses are considered to outweigh any conceivable beneficial effect of germinated grain.—W. M. Deans.

MERECALI, A. Le possibilità di impiego dei residui della lavorazione industriale delle carrube nell'alimentazione del bestiame. [The possible use of residues from the industrial processing of the carob bean in livestock feeding.] *Riv. Zootec.*, 1954, 27, 182-184.

After industrial processing of carob beans the germ, consisting of the embryo and cotyledons, is sometimes available for animal feeding. The percentage composition of carob germ is as follows: moisture 9.60, crude protein 40.99, crude fat 3.50, crude fibre 8.05, ash 5.58 and N-free extract 33.18. The crude protein is about 88 to 90 per cent. true protein and 80 per cent. digestible and the ash contains 7.33 per cent. Ca and 16.3 per cent. P. The vitamin content is somewhat low. The germ is thus a concentrate feed with high nutritive value despite its low Ca content.

Spent carob pulp after alcohol extraction has the following percentage composition on a dry matter basis: crude protein 10.40, crude fat 0.71, crude fibre 18.15, ash 4.94 and N-free extract 65.80. The moisture content is about 17 per cent. The pulp is comparable in composition to good quality hay, but its digestibility, in 3 trials with groups of 2 or 3 wethers, was extremely low.—D. Duncan.

FEDOTOV, P. A. K voprosu o molochnom konevodstve v usloviyakh Buryat-Mongolii. [Horse management for milk under conditions in Buryat-Mongolia.] *Konevodstvo*, 1953, No. 11, 37-40.

Vol. 25, No. 1

The Council of Ministers of the Buryat-Mongolian ASSR have decreed that 17 special koumiss farms should be organised in the region; a system of management of the mares and foals is discussed.

Mares' yield of milk was on the average 5 to 6 lb.

daily. The fat content of milk from mares of the local breed ranged from 1.4 to 2.3 per cent.

Mares should not be milked until their foals are 45 to 60 days old. Two hr. before the first milking the foals should be removed from their dams; at night they are pastured with their dams. During the hot hours of the day the foals are kept in a dry barn with plenty of fresh water and receive an additional daily feed of 1 kg. oats, 0.5 kg. wheat bran, 2 kg. grain residues and 15 to 20 g. salt. During the cool hours the foals are pastured on green grass near the barn. Under these conditions the foals grow and develop normally.

MAGIDOV, G. A. and CHALYUK, E. A. Ispol'zovanie kartofelya kak kormovoi kul'tury v konevodstvo. [The use of potatoes as a fodder crop

in horse management.] *Konevodstvo*, 1953, No. 12, 26-30. [Dept. Nutrit., VNIK.]

In these experiments the introduction of potatoes into the ration improved the digestion and metabolism of the horses and the results approximated to feeding under summer conditions. A ration for heavy horses and racehorses of 11 to 12 kg. cereal and legume hay, 5 kg. potatoes and 1.5 kg. oats improved the physiological condition of the horses and did not have a detrimental effect on their growth, development or production. In replacing concentrated foods with potatoes, the replacement should be at the rate of up to 3.5 kg. potatoes for 1 kg. oats. Raw potatoes are preferable to boiled ones, as boiling removes part of the N and mineral matter and part of the vitamins and has no effect on the assimilation of the nutrients.

DAVIS, H. P., PLUM, M. and BROST, B. Studies of herd management records. 2. Relation of gestation length to birth weight of Holstein calves of both sexes at various calvings. *J. Dairy Sci.*, 1954, 37, 162-166. [Dept. Dairy Husb., Univ. Nebraska, Lincoln.]

Data on 755 normal gestations and birthweights of 384 male and 371 female Holstein calves were analysed statistically. It was found that male calves were carried on the average for 278.9 days and female calves for 278.4 days. Birthweights of male calves were on the average 96.7 lb. and of females 90.3 lb. Differences in birthweight due to sex, calving sequence and gestation length were statistically significant.—J. N. Aitken.

BERZIN', YA. M. Novaya sistema kormleniya i vyrashchivaniya telyat. [A new system of feeding and rearing calves.] *Priroda*, 1954, No. 2, 49-54. [Acad. Sci., Latvian S.S.R.]

With 18 calves in the experimental and 11 in the control group, the experimental animals were started on skimmed milk from the 6th day after birth, and were entirely taken off whole milk on the 16th day. Immediately they were started on skimmed milk they were given vitamin concentrates, 300 units of vitamin A and 100 units of

vitamin D, daily per kg. liveweight. From the 16th day to 2 months each calf received 10 kg. skimmed milk daily. From the third month the skimmed milk was gradually reduced and at the end of the month they were only receiving 6 kg. Concentrates and hay were introduced into the ration from the 21st day. Both groups received salt and bonemeal. During the 3 months the experimental group received 182 kg. less whole milk per calf than the control group.

In further experiments at the end of 5 months the calves were fed entirely on plant foods, which contained sufficient natural vitamins, so that vitamin concentrates were not given. The calves were then fed on boiled potatoes, average 142 to 227 kg. each, fodder beet 171 kg., and sugar beet 19 kg. The concentrates part of the ration consisted of a mixture of oatmeal, wheat bran and various oil cakes, a total of 185 to 194 kg. per head. During the summer the roots were replaced by grass. When under cover the calves were given as much hay as they could eat. During the summer months they were out at pasture. The sheds were not heated.

Calves brought up on this system were superior to the control group in health and resistance to disease and developed into highly productive cows, producing not only more milk than their dams, but also milk with a higher fat content.

POUNDEN, W. D., CONRAD, H. R. and HIBBS, J. W. Observations on some substitutes for rumen inoculation. *J. Amer. Vet. Med. Assoc.*, 1954, 124, 394-396. [Dept. Vet. Sci., Ohio Agric. Exp. Stat., Wooster.]

N.A. and R., January 1955

Previous work had demonstrated the value of fresh rumen contents as an inoculum for the rumen of young calves fed on good quality roughage but only a limited quantity of grain. As substitutes for fresh rumen material, frozen fresh rumen juice and 3 commercial products advertised as containing viable rumen micro-organisms were investigated.

In vivo, their benefits were found to be not comparable to those of fresh rumen contents. *In vitro*, cellulose digestion tests indicated that the frozen product was only 80 per cent., and the one commercial product tested only 30 per cent., as efficient as the fresh material. Volatile fatty acids were produced by the frozen material, but scarcely at all by the commercial product; neither substitute promoted protein synthesis.

The frozen material, after thawing, contained microflora and microfauna morphologically similar to those of the original fresh material, but the protozoa were no longer motile. Examinations of aqueous solutions of the 3 commercial products did not reveal any of the indicator micro-organisms characteristic of the rumens of mature normal dairy cattle.

It was therefore concluded that, as rumen inoculants, the substitutes studied were inadequate. W. A. Greig.

BARTLEY, E. E., FOUNTAINE, F. C., ATKESON, F. W. and FRYER, H. C. Antibiotics in dairy cattle nutrition. 4. Comparative effects of different levels of crystalline aureomycin and a crude aureomycin fermentation product (Aurofac 2A) on the growth and well-being of young dairy calves. *J. Dairy Sci.*, 1954, 37, 982-989. [Dept. Dairy Husbandry, Kansas Agric. Exp. Stat., Manhattan.]

For previous work see Absts. 5185, Vol. 23; 5358, Vol. 24.

Ayrshire, Guernsey, Holstein and Jersey calves were divided into 4 groups of 8 animals each. One group was used as a control. Crude aureomycin was given to the second group in amounts calculated to supply 45 mg. aureomycin daily per 100 lb. liveweight. The remaining 2 groups received pure crystalline aureomycin at rates of 45 and 90 mg. daily per 100 lb. liveweight.

Calves given aureomycin were less affected by scour, pneumonia or other undiagnosed infections than the control calves. Bodyweight gains of the treated calves to 25 weeks of age were superior to those of the controls. From birth to 13 weeks the growth response of calves given the crude aureomycin was greater than that of the other 3 groups. During the last 11 weeks of treatment the growth of calves given 45 mg. pure aureomycin was significantly greater than that resulting from all other treatments. From birth to 25 weeks the growth

rate of calves given 90 mg. aureomycin was below that of the calves given 45 mg. aureomycin. There was no significant difference between the groups in the consumption of skimmed milk, hay and grain. The efficiency of feed utilisation of the calves given aureomycin was greater than that of the controls.—J. N. Aitken.

1353

HIBBS, J. W., CONRAD, H. R. and POUNDEN, W. D. A high roughage system for raising calves based on the early development of rumen function. 5. Some effects of feeding aureomycin with different ratios of hay to grain. *J. Dairy Sci.*, 1954, 37, 724-736. [Dept. Dairy Sci., Ohio Agric. Exp. Stat., Wooster.]

Three groups of Jersey calves were started on experiment at 3 days of age. Whole milk was given at the rate of 1 lb. per 10 lb. birthweight to 7 weeks of age. Mixed hay and a grain concentrate were given to the 3 groups, respectively, at one of the following hay to grain ratios: 4:1, 3:2 and 2:3. All calves were rumen-inoculated at 6 weeks of age as previously described (Abst. 624, Vol. 19).

Aureomycin was given at the rate of 15 mg. daily to 7 weeks of age to 4 calves in each group; from 7 to 12 weeks the rate was 20 mg. per lb. total dry feed. Some of the calves were continued on experiment to 26 weeks of age and were given a 2:1 or a 4:1 ratio of hay to grain. No aureomycin was given during the final phase of the experiment.

The calves given aureomycin made greater gains both in weight and in height at withers, irrespective of the ratio of hay to grain. They also consumed more total feed and estimated total digestible nutrients and net energy and utilised their feed more efficiently than untreated calves. Efficiency of feed utilisation was not influenced by the ratio of hay to grain. The advantages gained by the aureomycin-fed calves were lost during the period 12 to 26 weeks. During the final phase of the experiment calves on a 2:1 hay to grain ratio utilised their feed more efficiently than those on a 4:1 ratio.

From digestibility trials it was found that the increased efficiency during aureomycin feeding was not due to increased digestibility of dry matter, cellulose or protein. Percentage digestibility of protein and daily N retention increased as the amount of grain increased from the 4:1 to the 2:3 hay to grain ratio.

The average riboflavin content of both rumen juice and urine was higher in calves given aureomycin, but there was no difference in the vitamin B₁ content. Calves given aureomycin maintained a significantly higher level of blood sugar between 8 and 12 weeks. Changes in the proportion of

propionic and butyric acid in rumen liquor occurred as the result of aureomycin feeding and as a result of increasing the proportion of grain in the ration. Aureomycin inhibited the growth of the Hay II group of rumen bacteria. Increasing the amount of grain also decreased the number of bacteria in this group. It was concluded that the increased growth due to aureomycin was associated with an alteration in energy metabolism involving the microflora of the digestive tract.—J. N. Aitken.

1354

VOELKER, H. H., ALLEN, R. S., JACOBSON, N. L. and BLAKE, J. T. *In vivo* (dairy calves) and *in vitro* studies with surface-active agents. *J. Dairy Sci.*, 1954, **37**, 737-743. [Dept. Animal Husb., Iowa Agric. Exp. Stat., Ames.]

Addition of a cationic detergent to a milk replacement diet for young calves and of anionic, cationic and non-ionic detergents to the concentrate mixture for older calves had no effect on growth rate, feed consumption, incidence of diarrhoea, faecal pH, blood plasma fat or blood cell values. Studies *in vitro* showed that the addition of surface-active agents and penicillin to distilled water and rumen fluid reduced the surface tension; aureomycin and terramycin did not.—J. N. Aitken.

BRANSON, W. F., REID, J. T. and MILLER, J. I. The influence of certain factors upon the digestibility and intake of pasture herbage by beef steers. *J. Animal Sci.*, 1954, **13**, 535-542. [Cornell Univ., Ithaca, N.Y.]

During 4 months of the summer grazing season the following rations were given, respectively, to 3 groups each of 2 beef steers; pasture alone, pasture plus cane molasses and pasture plus ground yellow maize. Herbage intakes were measured by the use of chromium oxide and chromogen indicators. The estimated total intakes obtained by this method were compared with those estimated from total faecal collections. The results were in good agreement.

Digestibility of the herbage declined as the forage became more mature and increased as the aftermath became plentiful. Giving molasses depressed the digestibility of the herbage. Herbage intakes increased during periods of lush growth and declined when the herbage matured. Intakes of the supplements were greatest when the digestibility of the herbage was lowest. The steers receiving maize consumed the largest amount of feed and made the greatest weight gains. Total feed intakes and weight gains of the steers getting molasses were greater than those on pasture only.

NELSON, A. B., ROSS, O. B., DARLOW, A. E., CAMPBELL, W. D. and MACVICAR, R. W. Studies on winter rations for commercial beef cows. *Oklahoma Agric. Exp. Stat. Bull. No. B-418*, March 1954, pp. 22. [Oklahoma Agric. and Mech. Coll., Stillwater.]

Two systems of wintering beef cattle were compared over a period of 9 years. In the first the cattle were on pasture, mostly bluestem, all the year round, with a supplement of cottonseed cake for 5 months in winter. In the second the cattle were on pasture for 7 months only and then received prairie hay and a cottonseed cake supplement. Both systems proved satisfactory. In both alfalfa hay could replace cottonseed cake, 8 lb. of the former replacing 2.5 lb. cottonseed cake. The replacement would be profitable when the cost of alfalfa was less than one-third that of cottonseed cake. When alfalfa hay was given as a winter supplement the birthweight of calves was higher when the cows grazed all the year than when they received prairie hay during the winter.

1357

FRANKLIN, M. C. Feeding standards for beef cattle. C.S.I.R.O., Melbourne, Leaflet No. 7, 1953, pp. 16.

American and British feeding standards for beef cattle are tabulated and discussed in relation to Australian conditions where the optimum level food supplies and steady weight gains are frequently unattainable. When cattle are hand-fed during droughts special attention should be paid to the provision of calcium supplements and carotene-rich foods. Protein supply may also be deficient under these conditions and when rapidly maturing pasture is grazed, but the British standard of 1½ lb. digestible crude protein daily for a mature bullock is over-generous and wasteful of locally scarce feedingstuffs.—J. L. Corbett.

1358

MAWSON, W. F. Growth rates of beef cattle in tropical Queensland. *Queensland Agric. J.*, 1954, **78**, 301-307. [Cattle Husb. Branch.]

In this preliminary report the bodyweight gains of Shorthorn and Shorthorn × Hereford cross steers were compared with those of Shorthorn-Brahman and Shorthorn × Hereford × Brahman cross steers. Bodyweights were recorded monthly throughout 360 days. The breeds of purely British ancestry gained on the average 159 lb. per head and the Brahman crosses gained 231 lb. per head.

Environmental conditions and methods of management are described. It is proposed to continue the observations until the animals reach slaughter weight.—J. N. Aitken.

1359

McCONN, W. C. **Fattening yearling beef cattle on pasture.** *S. Dakota Agric. Exp. Stat. Bull.* No. 407, March 1951, pp. 16.

This trial was made in 2 phases. In the first the feeding value of brome hay, alfalfa hay and maize silage was compared in winter rations for beef calves. The second phase was planned to study the possibility and economy of fattening the same calves off summer pasture as yearlings. In each of 3 successive years 48 Hereford calves weighing about 450 lb. were used. A control group of 12 calves in each year was full-fed in dry lot throughout both winter and summer phases.

Both brome hay and maize silage when supplemented with 3 lb. shelled maize and a limited amount of alfalfa hay proved satisfactory for bringing the calves to a suitable state for finishing off pastures. A daily intake of up to 17 lb. alfalfa hay with 3 lb. shelled maize also proved satisfactory. Maize silage with limited alfalfa hay gave slightly higher daily gains than either of the other 2 rations. During the summer the feeding value of native grass, mainly Kentucky bluegrass, was compared with mixed brome and alfalfa pastures. Trials were made on both types of pasture to measure the value of giving maize throughout the grazing period as compared to grazing for 8 to 10 weeks and then giving maize and protein supplements. The calves full-fed in dry lot throughout the 2 periods reached slaughter weight a month before those receiving maize for the whole of the grazing season and 8 weeks before those getting maize for part of the season only. Calves which grazed the brome and alfalfa pasture with a supplement during the whole season gained 2.59 lb. daily; those pastured on native grass with an all-season supplement gained 2.26 lb. daily. The average daily gains of the calves which grazed the brome and alfalfa or the native pasture with half-season supplement were 1.99 and 1.95 lb. daily, respectively. Cattle fed in dry lot throughout cost more to feed, but the carcasses were better finished than those of cattle fattened on pasture.—J. N. Aitken.

1360

FRANKLIN, M. C. **Feeding trials with beef cattle.** C.S.I.R.O., Melbourne, Leaflet No. 8, 1954, pp. 16.

Australian beef is almost entirely grass-fed. Even on improved grazings the bodyweights of cattle of all ages remain stationary or decline during the long periods of pasture dormancy occurring in summer and autumn each year. Supplementary feeding during the droughts by grazing irrigated crops or by stall-feeding is only economical for the final finishing period. Maximum use must be made of home-produced fodders

compounded and fed according to British or American feeding standards. A ration containing 65 per cent. total digestible nutrients is a suitable maximum and more than 1.2 lb. digestible crude protein daily for a 1000-lb. beast is wasteful of scarce feed. Stall-fed animals must be of quiet temperament and have an ample supply of good water.—J. L. Corbett.

1361

FRANKLIN, M. C. **Feeding beef cattle for show.** C.S.I.R.O., Melbourne, Leaflet No. 9, 1954, pp. 8.

Recommendations are made on the quantities and qualities of feedingstuffs and methods of feeding for producing the high condition required in show cattle.—J. L. Corbett.

1362

KIDWELL, J. F., BOHMAN, V. R. and HUNTER, J. E. **Individual and group feeding of experimental beef cattle as influenced by hay maturity.** *J. Animal Sci.*, 1954, 18, 543-547. [Dept. Animal Husb., Univ. Nevada, Reno.]

The weight gains of weaned Hereford steers and heifers fed on early- or late-cut meadow hay were compared. A further comparison was made between those fed individually, in pairs, or in groups. The weight gains of animals on early-cut hay were significantly higher than those on late-cut hay of poorer quality. Steers and heifers receiving early-cut hay in pairs or in groups made greater weight gains than those fed individually. With late-cut hay the method of feeding made little difference to rate of gain. Animals fed individually on early-cut hay were more restless and had a lower feed consumption and more feed waste than those fed in pairs or groups.

BURROUGHS, W., CULBERTSON, C. C., KASTELIC, J., CHENG, E. and HALB, W. H. **The effects of trace amounts of diethylstilbestrol in rations of fattening steers.** *Science*, 1954, 120, 66-67. [Iowa Agric. Exp. Stat., Ames.]

Three experiments are reported in which diethylstilbestrol given by mouth to fattening steers for up to 84 days, at levels of from 2.5 to 10 mg. daily, produced a 35 per cent. increase in liveweight gain over that of control animals and a 20 per cent. reduction in feed required per 100 lb. gain.—J. S. Thomson.

1364

POPE, L. S., LONG, R. A., DARLOW, A. E. and MACVICAR, R. **Cowpeas as a protein feed for fattening steer calves.** *Oklahoma Agric. Exp. Stat. Bull.* No. B-399, May 1953, pp. 7. [Stillwater, Okla.]

Ground cowpeas were compared with cottonseed cake as a protein supplement to a ration of yellow maize, sorgo silage and alfalfa hay. The protein content of the cowpeas was 24.6 per cent. as compared with 42.8 per cent. for cottonseed cake, and in the daily ration of fattening steer calves 2.6 lb. of the peas replaced 1.5 lb. cake. Average daily gains were 2.15 and 2.19 lb., respectively. Cowpeas can replace cottonseed cake when their price is 76 per cent. of that of cottonseed cake.

DELAGE, J., LEROY, A. M. and POLY, J. Une étude sur les courbes de lactation. [Study of lactation curves.] *Ann. Zootech.*, 1953, 2, No. 3, 225-267. [Lab. Recherches Zootech., Inst. Nat. Agronom., Paris.]

The trend in milk yield from the 60th to the 250th day after calving is discussed. Mean production figures for each 10-day interval were obtained in 1949 from 146 lactations of cows of the black and white Friesian breed. These were picked out from a much larger number available, to avoid cases of inadequate feeding, and to obtain an even spread of calvings over the year. The cows were in their second, third or fourth lactation, were milked twice a day, and were served on the average 140 days after calving.

Linear, exponential, hyperbolic and parabolic curves were fitted to the data and the last of these was found to give the best fit over the period, the

exponential curve being second best. If the persistence of lactation is measured by the ratio of production in one month to that in the previous month, the exponential curve predicts a constant value for persistence; the parabolic curve agrees with the data in showing a slight increase over the period concerned. The use of persistence, averaged over the period from maximum production to about 4 months after conception, is advocated as a convenient parameter to describe the course of milk production.

The data used were not adequate for a study of the first 60 days of lactation, in which the yield attained its maximum value in most of the cows. In the final stage of lactation, from the 250th day to somewhat over the 300th day, there is a comparatively sharp drop in yield and the timing of this fall is shown to be related to the service period.

A detailed survey is made of the literature on the subject and the authors' results are discussed in relation to those of others.—I. McDonald.

1369

LEGATES, J. E. and LUSH, J. L. A selection index for fat production in dairy cattle utilizing the fat yields of the cow and her close relatives. *J. Dairy Sci.*, 1954, 37, 744-753. [Dept. Animal Husb., Iowa State Coll., Ames.]

In selective breeding of cattle for the improvement of fat production it may be useful to consider not only the lactation records for the individual cow, but also those for other cows closely related to her. To discover how best to combine this information give to an index of breeding value, use was made of 23,330 lactation fat yield records from 12,405 Jersey cows in 293 herds in the United States. From analyses of the intra-herd variability, measures were obtained of the repeatability of fat records of the same cow, of the correlations between fat records of maternal and of paternal half-sisters, and of the correlation between daughter and dam, the last showing the heritability of fat production. In the course of the analyses it was found that the herd component accounted for 39 per cent. of the total variance, and that year-to-year variations accounted for 8 per cent. of the intra-herd variance but tended to cancel out over the average for all herds. The index devised from these measures is given in the form of a linear combination of the estimated real producing abilities of the cow and her dam and of the sums of those of her daughters, maternal sisters, and paternal sisters, with coefficients depending on the numbers available in each case.

Estimates are obtained, for a variety of situations, of the genetic improvement in fat production which might be expected from the use of the index as a basis for selection, and this is compared

with the improvement to be expected from the use of the cow's own performance. It is concluded that in practice progress would be about 1.10 to 1.15 times faster by the method described, the exact ratio depending on the information available.—I. McDonald.

BALCH, C. C., BALCH, D. A., BARTLETT, S., COX, C. P., ROWLAND, S. J. and TURNER, J. *Studies of the secretion of milk of low fat content by cows on diets low in hay and high in concentrates.* 2. The effect of the protein content of the concentrates.

BALCH, C. C., BALCH, D. A., BARTLETT, S., HOSKING, Z. D., JOHNSON, V. W., ROWLAND, S. J. and TURNER, J. 3. The effect of variations in the amount and physical state of the hay and a comparison of the Shorthorn and Friesian breeds. *J. Dairy Res.*, 1954, 21, 165-171; 172-177. [Nat. Inst. Res. Dairying, Univ. Reading.]

For Part 1 see Abst. 1375, Vol. 22.

2. Twenty cows, 14 Shorthorn, 1 Guernsey and 5 Friesian, mostly in early lactation, were in 4 groups given one of 5 treatments in the experimental period of a study which lasted 13 weeks in all. For 2 preliminary control weeks all cows got 18 lb. hay with 4 lb. per gal. of a concentrate mixture, of decorticated groundnut cake 3, flaked maize 10 and weatings 7 parts by weight and 2 per cent. of a mineral mixture. The period of weeks 3 to 9 was experimental with one group A continuing as control. In the remaining 4 groups all cows received only 4 lb. hay with additional 6 lb. concentrates to compensate for the reduction and of these, 2 groups, B and C, were given a mixture which was high and the other 2 groups, D and E, one which was low in protein. The constituents of these mixtures, in parts by weight and with the high protein mixture quoted first, were, barley meal, 3, 3; decorticated groundnut cake 6, 1; flaked maize 6, 12; maize gluten feed, 3, 0; weatings 3, 3; protein contents were 22.3 and 11.6 per cent., respectively. For weeks 7 to 9 cows in groups C and D were given daily 1 lb. crude fibre as 10 lb. delignified straw pulp. During weeks 10 and 11 all returned to the treatment given in the first period, and the experiment ended with observations made during a 2-week period of grazing.

In the period of low intake of hay loss of appetite was common for the first few days but in only 3 cows did it persist for more than 4 days. Effects on yield were slight and not statistically significant; only the change to grazing resulted in an increase of production. Reduction in intake of hay was followed by a fall in both percentage and yield of fat, but with the concentrate mixture high

in protein the fall was slower than with the low-protein mixture. The addition of the straw pulp led to no increase in milk fat production. There was evidence that the fall in fat percentage in milk was less the more advanced the stage of lactation of the cow.

3. In an experiment which lasted for 14 weeks 16 cows were given for the first 3 weeks 16 lb. hay daily with the control concentrate mixture as in Part 2. Of the 7 weeks of experimental period 3 were spent in changing the diets gradually, by which time groups A, B, C and D, each of 3 Shorthorn cows, were receiving 12, 8 and 4 lb. long hay and 8 lb. ground hay, respectively, and the fifth group E with 4 Friesians, 4 lb. long hay. All continued to get the control concentrate mixture which contained 16.1 per cent. protein and, to compensate for the reduction in hay, another mixture of barley meal, dried brewer's grains, dried sugar beet pulp, flaked maize and weatings, 3, 1, 1, 3 and 2 parts by weight and with protein content 10.1 per cent., was prepared and given at rates of 4, 6, 8, 6 and 8 lb. to groups A to E, respectively. For the last 3 weeks of the experiment hay was restored to the 16 lb. level and the giving of the second concentrate mixture was stopped. Only the fat content of the milk was estimated.

Changes in diet did not produce noticeable changes in rates of decline of milk yield. Reduction of the hay to 12 lb. did not affect to any appreciable extent the fat percentage of the milk but changes to less than that amount resulted in its falling. Fat yield also fell in groups B to E by amounts estimated, from comparison with the control group, to be 28.4, 29.3, 55.2 and 36.2 per cent., respectively. The fall in fat yield was greater with ground than with the same amount of long hay. The fall in fat content of the milk of the Friesian cows given 4 lb. hay was greater than, but not significantly different from, that in the corresponding group of Shorthorn cows.

SPRAIN, D. G., SMITH, V. R., TYLER, W. J. and FOSGATE, O. T. The effect on milk and fat production of injections of oxytocin at alternate 14-day periods during lactation. *J. Dairy Sci.*, 1954, 37, 195-201. [Dept. Dairy Husb., Univ. Wisconsin, Madison.]

Oxytocin was administered intravenously to 7 Holstein cows. Each cow was milked through 10 control and 10 experimental periods. Mean daily milk production was 3.6 lb. higher during the treatment periods than during the control periods. The greatest increases were obtained from cows which had shown lack of persistency in previous lactations. Treatment had no significant effect on butterfat percentage.—J. N. Aitken.

1372

THOMAS, J. W., COPLAND, D. V., KEYES, E. A. VAN HORN, A. G. and MOORE, L. A. **Effects on economy and efficiency of milk production when thyroprotein is fed for a short period of time to milking cows.** *J. Dairy Sci.*, 1954, **37**, 877-888. [Dairy Husb. Res. Branch, U.S. Dept. Agric., Washington, D.C.]

Thyroprotein was given at the rate of 15 g. per head daily, for 60 days to 26 Holstein and Jersey cows. During this time the production of fat-corrected milk by treated cows increased while that of a group of control cows decreased. When thyroprotein was withdrawn milk production fell to below normal. Giving extra grain to cows receiving thyroprotein did not greatly increase persistency. In some cows turned out to pasture immediately after the withdrawal of thyroprotein there was no decrease in milk production. The butterfat percentage of treated cows increased during the experimental period. All treated cows lost weight. There was no increase in roughage consumption by the treated cows.

The efficiency of production of the treated cows whose milk yields fell below normal after the withdrawal of thyroprotein was less than that of the controls when total production over the experimental and post-experimental periods was considered.—J. N. Aitken.

1373

SEN, K. C., PREMACHANDRA, B. N., MURTHY, G. K., DASTUR, N. N. and NARAYAN, D. **The effect of feeding iodinated casein on yield and composition of milk.** *Indian J. Dairy Sci.*, 1954, **7**, 49-63. [Indian Dairy Res. Inst., Bangalore.]

Iodinated casein was given, for 10 weeks during the declining phase of lactation, at the rate of 25 g. per 1000 lb. bodyweight to 3 Gir, 3 Sindhi and 8 Ayrshire × Sindhi cows. After a rest period of 9 weeks, 4 of the cows were given a repeat dose for a further period of 5 weeks. The ration consisted of 30 lb. Guinea grass, 20 lb. Rhodes grass, 5 lb. ragi straw and a concentrate mixture at the rate of 1 lb. for 3 lb. of milk produced. Bodyweights, milk, butterfat and solids-not-fat production were recorded.

Bodyweights declined during treatment and increased when iodinated casein was withdrawn.

Milk production increased during treatment when compared with either the pre-treatment yield or the estimated normal yield. The increase reached a peak after 3 weeks of treatment and then decreased. The rate of decrease was accelerated when iodinated casein was withdrawn.

Butterfat and solids-not-fat percentages and total fat yield increased during treatment. Cows given a second dose of iodinated casein in late

lactation gave a better response in milk yield and butterfat percentage than when treated earlier in lactation. The response of the Ayrshire × Sindhi cows was better than that of the other breeds.

MAQSOOD, M. **Galactopoietic action of thyroxine in cattle kept in subtropical countries.** *Nature*, 1954, **174**, 185. [Dept. Physiol., Punjab Coll. Animal Husb., Lahore, Pakistan.]

A buffalo and a cow received by mouth daily for 4 weeks 15 g. thyroprotein containing 0.75 per cent. L-thyroxine, during October and November in West Pakistan. Two comparable animals were selected as controls. The tests were started 8 weeks after calving in the buffaloes and 20 weeks in the cows. All 4 animals were milked twice daily and the milk yields and rectal temperatures were recorded.

Atmospheric temperatures ranged from 63.0° to 93.9° F. during October and from 50.0° to 82.0° F. in November, and humidity was from 56 to 69 per cent. Average daily yields of milk from the control and treated buffaloes were 22.7 ± 0.027 and 27.1 ± 0.018 lb., respectively. Statistical analysis showed that the increase due to treatment was highly significant. The average daily milk yields of the control and treated cows were 12.0 ± 0.11 and 13.7 ± 0.24 lb., respectively, an increase not statistically significant. The body temperatures of the control and treated animals showed no difference. It is suggested that the thyroxine treatment of the cows might have had greater effect if started earlier in lactation.

JUCKER, H. **Zur Mineralstoffversorgung beim Rindvieh. [Supplying minerals to cattle.]** *Schweiz. Landwirtsch. Ztschr. Die Grüne*, 1954, No. 1, 3-8. [Inst. Haustierernährung ETH, Zürich.]

Physiological reasons for supplying minerals are briefly outlined and the common feedingstuffs are reviewed as sources of Ca and P and compared in a diagram. The proper salts to balance rations are defined; every animal should have salt (NaCl) daily and AIV silage should be neutralised by 50 to 100 g. of a mixture of 75 per cent. calcium carbonate and 25 per cent. soda.—I. Leitch.

1376

DAVIS, R. F., WILLIAMS, C. and LOOSLI, J. K. **Studies on sulfur to nitrogen ratios in feeds for dairy cows.** *J. Dairy Sci.*, 1954, **37**, 813-818. [Dept. Animal Husb., Cornell Univ., Ithaca, N.Y.]

Representative samples of 21 feedstuffs used in preparing concentrate mixture for dairy cows were analysed for the usual constituents. Total S and

N.A. and R., January 1955

the N : S ratio were also estimated. The results are presented in tables. In an experiment with 19 Holstein cows the addition of sodium sulphate to a concentrate mixture containing urea did not increase the production of fat-corrected milk.

ZELTER, Z. Le rôle nutritionnel, chez la vache en lactation, des acides acétique et butyrique formés au cours de l'ensilage. [Nutritional role in the lactating cow of acetic and butyric acids formed during ensiling.] *Ann. Zootech.*, 1953, 2, No. 2, 105-147; No. 3, 197-224; No. 4, 303-364. [Lab. Recherches, Inst. Nat. Agronom., Paris.]

Part 1 of this Mémoire gives an extensive review of the literature relating to the derivation and formation of milk fat and Part 2 reviews techniques applicable to the problem in hand. It includes feeding standards for dairy cows, analytical methods for feedingstuffs and milk, and the interpretation of metabolism experiments. In Part 3 experiments are described with 2 groups, each of 7 carefully matched Normandy cows, given a basal diet of either half-sugar beet or silage in 3 successive periods on the plan : Group 1, beet, silage, beet; Group 2, beet, beet, silage. The beet was given, 45 kg. daily, with 4 kg. meadow hay and a concentrate mixture of linseed and groundnut cake, wheat bran, barley, oats and a mineral mixture, according to individual needs. The silage was of sugar beet pulp and tops and it replaced the half-sugar beet weight for weight. In each group the silage period showed a milk yield above expectation, and fat production rose more than yield. The results are statistically analysed and are judged on the slope of a theoretical line of decline of lactation.

Possible explanations are discussed. There was at all times a supply of energy surplus to needs for maintenance and milk produced, and the cows put on weight. Protein was present also in excess of needs, but digestible fat was not at any time above the minimum required for maintenance of mammary function, "seuil minimum indispensable," i.e. about 0.5 g. per kg. liveweight. The effect of silage is therefore attributed to the ingestion with the silage of 499 or 464 g. acetic and 351 or 333 g. butyric acid.

In a second experiment the same or similar cows, after 63 days' preliminary records, were divided into 3 groups, of which 1 was control and the others had Ca acetate and butyrate added to the basal diet or again had beet replaced by silage. The control group had an addition of CaCO_3 , 250 g. to balance the Ca in the ration with fatty acids, which contained 237 g. Ca acetate and 214 g. Ca butyrate. Again the fatty acids and silage each gave a yield of milk and fat in excess of expectation.

Vol. 25, No. 1

For instance, the milk yield of the control group in the second period was 23.8 per cent. and fat production 24.6 per cent. less than in the first period; those of the fatty acid group were only 6.4 and 7.1 per cent. less and of the silage group, 10.6 and 11.0 per cent. less.

Individual performances and possible explanations are discussed.

A third similar experiment compared the effects of acetic acid alone, butyric acid alone and butyric and pyruvic, or acetic and butyric, acids together. Acetic acid (400 g. Ca acetate) had an immediate effect, arresting the decline of yield, and there was a slight increase in percentage of fat. Butyric acid alone had no detectable effect, but butyric acid with pyruvic acid had a small effect and with acetic acid an effect comparable with that of acetic acid alone.

In summary the effect is assessed as chiefly on yield, less on percentage fat in milk, and this is attributed to a minimum fat requirement not supplied by the basal ration. An addendum condemns beet as a feed for milk production on account of its lack of fat.—I. Leitch.

1378

HUFFMAN, C. F. and DUNCAN, C. W. The nutritive value of corn silage for milking cows. *J. Dairy Sci.*, 1954, 37, 957-966. [Dept. Dairy Chem., Michigan State Coll., East Lansing.]

The effect on fat-corrected milk production of cows of replacing part of the hay, in an all-hay ration, with maize silage was studied in 23 trials. Milk production increased when maize silage was given. It was concluded that maize silage supplies the unidentified grain factor(s) needed to balance the total digestible nutrients in roughage (Abstr. 3036, Vol. 22).—J. N. Aitken.

1379

HUFFMAN, C. F., DUNCAN, C. W., DEXTER, S. T. and CHANCE, C. M. The feeding value of red clover conserved as hay and as silage in respect to milk production. *Quart. Bull. Michigan Agric. Exp. Stat.*, 1954, 36, 391-400. [Dept. Dairy.]

A crop of 90 per cent. red clover, 5 per cent. timothy and 5 per cent. brome grass was cut and each alternate windrow was made into silage, the remainder into hay. Molasses was added to the silage at the rate of 50 lb. per ton. The contents of protein and crude fibre in both fodders were approximately the same when compared on the dry basis but silage had a higher percentage of ether extract. The coefficients of digestibility of the dry matter, crude fibre and N-free extract were in good agreement. The protein coefficient was higher for the hay than for the silage. The reverse was true for ether extract. There was no

significant difference between the fodders in digestible protein or total digestible nutrients when compared on the dry basis. Silage had a higher content of carotene.

The results from a 30-day double reversal trial with 2 groups of 4 cows fed during alternate periods on either hay or silage supplemented with equal amounts of maize showed that there was no significant difference in the amounts of fat-corrected milk produced or in the amount of total digestible nutrients consumed. The fodders proved equal for milk production when grain was not included in the ration. Since previous reports (Absts. 3036, Vol. 22; 3657, Vol. 23) had shown that mature hay was deficient in an unidentified lactation factor, it was concluded that in this case both fodders were of equal value as sources of this factor.—J. N. Aitken.

MARKOVA, K., AL'TMAN, A. and SIMON, E. Korn-
lenie korov sakharnoi svekloi i sostav moloka.
[Feeding sugar beet to cows and the composition
of their milk.] *Mol. Prom.*, 1954, 15, No. 4,
38-39. [All-Union Sci. Res. Inst. Animal
Breeding.]

Cows producing milk with a high butterfat content react better to sugar beet feeding than do cows producing milk with a low butterfat content. In one experiment both yield and butterfat content rose when the cows were given sugar beet. In 2 experiments sugar beet led to a decrease in the size of the fat globules and an increase in the number of small globules. Giving potatoes to cows had little effect on the average diameter of the fat globules. From experimental results it is assumed that not all animals respond equally to the introduction of sugar beet into the ration. Of the 2 breeds of cows in an experiment the fat content of the milk produced by Latvian Brown cows increased to a considerably higher degree than did that of the other breed when both were given sugar beet.—H. Scherbatoff.

HOLMES, W. High milk yields per acre from grass-
land. *J. Brit. Grassland Soc.*, 1954, 9, 17-27.
[Hannah Dairy Res. Inst., Kirkhill, Ayr.]

Potential milk yields per acre are considered in the light of evidence obtained from experiments on small grass plots of varying basic fertility and clover content, and from a dairy cow grazing trial. The increase in yield per acre of herbage dry matter, starch equivalent and protein was found to be almost linearly related to the supply of up to 300 lb. elemental N in fertiliser per acre. At this level, under the conditions of climate and soil, it is suggested that 50 cwt. starch equivalent per acre should be obtainable with good methods of utilisation by conservation and grazing. Results from the grazing trial showed that this level of production was achieved on heavily fertilised pastures which received 568 lb. of fertiliser N over 3 years. The yields, on average, were about 50 per cent. above that of pastures receiving light dressings totalling 159 lb. of fertiliser N over 3 years. Total N supply was estimated to be increased considerably by the animals' excreta. From these experiments, and calculations on the productivity of different grass farming systems, the inter-relationships between available N, yields of dry matter and starch equivalent per acre, and carrying capacity and milk yield per cow and per acre are expressed graphically. Higher production per acre can be obtained either by raising milk yield per cow or by increasing grass yield. From examination of the graph the latter course is considered to be the more effective.—J. L. Corbett.

BERGE, S. Mjølkeavdrått på landbrukshøgskolens
gårdsbruk 1858-1953. [Milk yield on the
college farm 1858-1953.] *Meld. Norges Land-
brukshøgsk.*, 1954, 34, 345-372. English sum-
mary.

The records cover number and liveweight of cows, feed consumption, total milk produced and yield per cow, and, less completely, fat and solids-not-fat of milk. The herd began with 20 Ayrshires and 20 Telemark cows, but its subsequent history, in terms of breed, is not described. Cows have increased in weight; fat percentage has risen only since about 1940, and yield per cow has about doubled since the beginning of the century. Cost of production in terms of feed units per kg. milk does not seem to have changed.—I. Leitch.

HANCOCK, J. Studies of grazing behaviour in
relation to grassland management. 1. Varia-

N.A. and R., January 1955

tions in grazing habits of dairy cattle. *J. Agric. Sci.*, 1954, 44, 420-433. [Ruakura Animal Res. Stat., N.Z. Dept. Agric.]

Ten sets of lactating twin cows grazed on different pastures and their grazing behaviour is described over 4 periods of 14 days. Grazing times were short with an abundant supply of high-quality grass and increased when the grass was longer or the supply decreased; long when the grass was abundant but of mixed quality, and longest when the grass was very short, whether of good or poor quality. Ruminating time was short on good quality grass even when the supply was scanty, and was prolonged by poor quality grass.

Change of pasture was followed by rapid adjustment of grazing habits. Weather had little effect.

REPRODUCTION

1386

BANE, A. Studies on monozygous cattle twins. 15. Sexual functions of bulls in relation to heredity, rearing intensity and somatic conditions. *Acta Agric. scand.*, 1954, 4, 95-208. [Dept. Obstet., Royal Vet. Coll., Stockholm.]

The literature is reviewed. Six pairs of identical twin bull calves of the Swedish Red and White breed were reared to 1½ years on high, medium or low planes of nutrition. After that time they all received equal amounts of feed. Study of sexual activity began at 1½ years when semen collections were made once a week and measurements were made of volume, sperm concentration, sperms per ejaculate, initial sperm motility, duration of motility and sperm morphology. State of health

was closely watched and post-mortem examination made of sex organs, pituitary, thyroid, parathyroid, adrenal and bones of the sacro-iliac joint.

The rearing ration for all planes was of milk, concentrates, roots and hay, the higher planes receiving more concentrates, and supplied 1601, 2176 or 2634 feed units daily. Owing to accident one pair of calves had to be destroyed at 28 months, 3 pairs were used for 50 to 58 months, and 2 pairs for 82 to 89 months.

Higher feeding intensity was reflected in increased rate of growth during the rearing period to 18 months, but at 36 months this difference had disappeared.

There was no significant linear regression between rearing intensity and any sperm characteristic, but there was a tendency to higher frequency of abnormal sperm heads with increasing feed intensity. There were large genetic differences between pairs in sperm characteristics.

Rearing intensity had no effect on mating behaviour. Impotence occurred in 3 pairs at the same age for twins of the same pair.

High rearing intensity showed an increase in size of the testicles and epididymides in 3 of the pairs and of the seminal vesicles in 5. The lower weight of the adrenals in the high-plane group is attributed to decreased activity of the thyroid.

J. S. Thomson.

1387

KÁBET, J. and ŠTOURAČ, J. Výsledky pokusů s krmením býků s ohledem na jakost semene. [Results of experiments on the feeding of bulls with regard to the quality of sperm.] *Spisy fak. vet.*, 1953, 22, 77-87. [Inst. Diet., Vet. Fac. Agric., Univ. Brno.]

Increasing the amount of minerals in the feed of bulls caused an increase in the vitality of the sperm even if the animals had received during the preceding period a sufficient amount of minerals. A supplement of vitamin C had a similar effect.

BUOY, L. L., GARRIGUS, U. S., FORBES, R. M., NORTON, H. W. and JAMES, M. F. Arsenical supplements in lamb fattening rations. *J. Animal Sci.*, 1954, 13, 668-676. [Dept. Animal Sci., Univ. Illinois, Urbana.]

Vol. 25, No. 1

In trials involving 160 feeder lambs, supplements of arsenic acid were given at levels of 0-002, 0-004, 0-006, 0-012 and 0-024 per cent. of the total ration and potassium arsenite and arsenic acid at similar levels of arsenic content. None of these compounds added to high- or low-quality rations consistently increased weight gains, nor did they reduce the numbers of coccidia. Treatment did not appear to affect rumen microflora, prothrombin time, wool growth, liver, kidneys or adrenal glands. No toxic effect or influence on appetite was noted.

J. C. Gill.

1390

WHITING, F., CLARK, R. D. and ALLEN, C. E. Synthetic estrogen in lambs. 1. The effect of diethylstilbestrol on weight gains and carcass grades of feeder lambs.

ELLIS, P. J., ALLEN, C. E. and WHITING, F. 2. The diethylstilbestrol content of treated lamb tissues. *Canad. J. Agric. Sci.*, 1954, **34**, 288-291; 292-298. [Exp. Stat., Lethbridge, Alta.]

1. Two groups of feeder lambs, average weight 57 lb., were used, one group having an implant of 12 mg. diethylstilbestrol subcutaneously. After 106 days on a ration of alfalfa hay and grain to appetite the treated group showed the greatest daily liveweight gain, 0.50 lb. as against 0.40 lb. for the control, the highest carcass weight, 51.2 lb. as against 50.2 lb., but the lowest dressing percentage, 46.4 per cent. as against 49.9 per cent. Feed efficiency based on feed consumption per 100 lb. liveweight gain was best in the treated group, but there was no difference between the groups when efficiency was expressed per 100 lb. carcass gain. In the treated group the moisture content of the round of leg was 55 per cent. and in the control 50.8 per cent.; corresponding figures for ninth and tenth rib portion were 38.8 and 35.1 per cent. It is concluded that the increase in bodyweight after diethylstilbestrol treatment is due to increased moisture content of the tissues and to a greater amount of offal.

2. Estimation of residual oestrogen activity of kidney fat, shoulder muscle, and liver 15 weeks after implantation of diethylstilbestrol showed, from changes in the uterine weights of weanling rats after injection, that the amounts did not exceed 7.1 μ g. per 100 g. kidney fat, 2.8 μ g. per 100 g. shoulder muscle and 4.0 μ g. per 100 g. liver.

J. S. Thomson.

1391

KEITH, T. B., LEHRER, W. P. (Jr.) and HEDEGAARD, M. T. Peas—a source of protein for sheep. *Univ. Idaho Agric. Exp. Stat. Res. Bull.* No. 24, October 1953, pp. 15.

Five groups of ewe lambs weighing 65 to 100 lb. were fed to appetite for 63 days on a low-protein roughage and a concentrate of barley and oats with (1) Austrian peas (*Pisum arvense*), (2) Austrian peas plus 0.3 per cent. DL-methionine, (3) Alaska peas (*Pisum sativum*), (4) Alaska peas plus DL-methionine. A fifth group had a concentrate of cereals and soya bean oilmeal. Average daily gains, in the above order, were: 0.38, 0.38, 0.30, 0.40 and 0.34 lb., and feed consumption per 100 lb. gain 784, 778, 907, 762 and 841 lb. Similar results were obtained in paired feeding trials.

It is concluded that Alaska peas are deficient in methionine. When such a supplement is added they have a feeding value equal to that of Austrian peas.—J. S. Thomson.

1392

KEDROVA, S. I. O skarmivanii karakul'skim ovtzam izmel'chennykh grubosteb'chatykh kormov. [Feeding finely-chopped coarse-stalked fodder to Karakuls.] *Karakul. Zverovodstvo*, 1953, **6**, No. 6, 31-34. [All-Union Sci. Res. Inst. Karakul Management.]

Hay made from these fodders was chopped and some of it ground to a fine meal. If of necessity sheep had to be given this kind of fodder during the winter without concentrates, it was eaten more readily when chopped and ground than in the form of hay. When the sheep need a more nutritious feed the meal should be mixed with concentrates. Less energy is required to chew and digest the chopped hay or meal and therefore the sheep put on more weight than with whole hay. It is concluded that the amount of fodder eaten depends not only on its composition, but also on the method of its preparation and feeding.

JORDAN, R. M. and WEAKLY, H. Feeding Dakota lambs. Results of feeding trials at the Newell Field Station. *S. Dakota Agric. Exp. Stat. Bull.* No. 403, June 1950, pp. 7.

Results of lamb feeding trials over 6 years showed that mortality, average daily gain, average daily feed consumption and efficiency of feed conversion were not affected by the number of lambs per group or the area allotted per lamb or by feeding twice compared with 3 times daily. Lambs self-fed on 70 per cent. maize and 30 per cent. chopped alfalfa had a higher death rate but made higher average gains and were more efficient in feed utilisation than lambs fed on 70 per cent. barley and 30 per cent. chopped alfalfa. Lambs hand-fed on maize and alfalfa were more efficient and made gains equal to or greater than those of lambs hand-fed on barley and alfalfa. Death losses were equal. Chopped hay showed no advantage over long hay.—J. C. Gill.

1394

MCCLYMONT, G. L. Intensive hand feeding for growing and fattening sheep. *Agric. Gaz. N.S.W.*, 1954, **65**, 301-305. [Nutrit. Res. Lab., Vet. Res. Stat., Glenfield, N.S.W.]

The intensive hand-feeding of drought-stunted lambs would appear to have commercial possibilities in Australia. Two experiments are reported, in one of which the hand-feeding of alfalfa chaff alone for 56 days produced liveweight gains of 16.8 lb. as compared with 1.9 lb. with wheat chaff, and a mixture of alfalfa chaff and oat grain produced gains of 20.5 lb. as compared with 10.6 lb. with wheat chaff and oats.—J. S. Thomson.

- LEWIS, C. J. **Observations on the production of fat lambs in Anglesey 1952 and 1953.** *Dept. Agric. Econ., Univ. Coll. Wales, Aberystwyth*, 1954, pp. 42. Price 3s.

An increase in sheep population since 1945 and heavier stocking than in 1939 are reported. The flying flock system is the basis of the industry, and the crossbred lambs produced are fattened on grass only. Marketing analyses are reported in detail and show that in 1952 and 1953 18.7 and 24.6 per cent., respectively, of the total sales of fat lambs were graded at 41.7 lb. estimated dead weight (E.D.W.) and 39.5 lb. E.D.W., respectively, during June, i.e., 1 lb. heavier than the average for each of these years. Lambs sold after June would have made more profit if they had been sold earlier. Average E.D.W. of lambs fell from mid-July to mid-November. Data are included of a sample of 28 Anglesey flocks which show that there is a high ewe mortality and that "high margin" farms produce a higher percentage of lambs to ewes tupped and sell heavier lambs than "low margin" farms.—J. C. Gill.

1396

- JORDAN, R. M. and SHAFFHAUSEN, D. D. **Effect of Somatotropin on milk yield of ewes.** *J. Animal Sci.*, 1954, **13**, 706-710. [S. Dakota Agric. Exp. Stat.]

Six ewes given an intramuscular injection of 25 mg. Somatotropin once daily for 6 consecutive days produced, on the seventh day, 40 per cent. more milk than 6 control ewes. A highly significant increase occurred in the percentage of fat in the milk of the treated animals and a non-significant decrease in the non-fat solids. In a second trial 4 ewes milked twice weekly over a 3-week period of daily injections gave an increase of 22 per cent. in milk yield and of 2.3 in percentage units of fat. Both increases were highly significant. Feed consumption of 3 of the ewes increased during treatment. In both trials milk yield and fat percentage returned to pre-treatment levels 3 to 10 days after treatment was completed.

- WHITING, F., SLEN, S. B., BEZEAU, L. M. and CLARK, R. D. **The sulphur requirements of mature range ewes.** *Canad. J. Agric. Sci.*, 1954, **34**, 261-268. [Exp. Stat., Lethbridge, Alta.]

Ninety-six mature grade Romney ewes were used in an 8-month trial in which rations were given containing sulphur at levels of 0.08 per cent. (basal ration), 0.13 and 0.17 per cent. (basal and organic sulphates), 0.13 and 0.17 per cent. (basal and elemental S) and 0.13 per cent. (basal and methionine). There was no significant difference

between ewes on the different levels in respect of weight gain, wool production, lamb production and sulphur content of blood serum, colostrum or wool. Results indicated that 0.1 per cent. total S in the ration supplies sufficient for mature ewes to produce normal lambs and fleeces.—J. C. Gill.

- AYER'YANOV, I. YA. **Kachestvo karakulya v zavisimosti ot uslovii kormleniya i soderzhaniya ovetz.** (Opyt perevoda karakul'skikh ovetz iz Kazakstana v Turkmeniyu.) [Karakul quality in relation to conditions of feeding and management. (An experiment in transferring Karakul sheep from Kazakhstan to Turkmenistan.)] *Karakul. Zverovodstvo*, 1953, **6**, No. 4, 9-15. [All-Union Sci. Res. Inst. Karakul Management.]

The improvement in the quality of the wool when sheep were moved to Turkmenistan is attributed very largely to improved feeding. The pastures of Turkmenistan provide more continuous and better feeding than do the Kazakhstan pastures which are quite good in summer and autumn but deteriorate in the late winter. On the Turkmenistan sovkhos the winter deficiencies of the pasture were made up by giving the sheep coarse fodders and concentrates. It is therefore essential that under Kazakhstan conditions both coarse fodders and concentrates should be given, particularly during the second half of the winter when the feeding value of the pastures is low.

- FERGUSON, K. A. **Prolonged stimulation of wool growth following injections of ox growth hormone.** *Nature*, 1954, **174**, 411. [Dept. Animal Pathol., Milton Rd., Cambridge.]

Wool growth in 2 Romney Marsh and 2 Suffolk ewes, injected daily for a fortnight with an extract of ox anterior pituitary, was significantly greater than in controls during the first week of injections. A significant increase was maintained for 14 weeks after injections had stopped. In a second experiment 4 ewes received 5 mg. ox growth hormone for 5 weeks. A significant increase in wool growth over controls resulted during the injection period and for the following 29 weeks. In this trial the increase was greater in the Suffolk than in the Romney Marsh ewes. In Lincoln ewes wool growth was stimulated during the injection period only.—J. C. Gill.

- CLARK, G. L. and BUHRKE, V. E. **Effect of elemental sulfur in the diet on load-extension hysteresis in single wool fibers.** *Science*, 1954, **120**, 40. [Dept. Chem., Univ. Illinois, Urbana.]

An apparatus was designed especially for measuring, under suitably comparable circumstances, the elongation of single wool fibres produced by the application of known loads. Reproducibility of stress-strain curves was good with both addition and removal of weights.

Wool samples were obtained from sheep fed to appetite on a basal ration with 0.05 per cent. S. Powdered S was added in 6 amounts from 0.20 to 0.70 per cent. With no S added the loop of tension

and relaxation was extremely narrow; with increase in S the area of the loop increased and at the 0.7 per cent. level it was 3 times that at the 0.2 per cent. level. It is concluded that the additional S was metabolised and added to the disulphide linkages between the keratin molecules of the fibres.

The apparatus and findings are to be described elsewhere in more detail.—D. Harvey.

1401

NATIONAL RESEARCH COUNCIL, U.S.A. Nutrient requirements for domestic animals. 2. Nutrient requirements for swine. Publ. No. 295, revised August 1953, pp. 28. Price \$0.50.

This publication is a revision of an edition published in 1950 (Abst. 3093, Vol. 22). The tables of nutrient requirements have been extended to include 25-lb. pigs. Crude protein requirement has been reduced for growing pigs and lactating adult sows, but increased for pregnant adult sows. For breeding stock and several weight groups of market stock both Ca and P requirement have been increased. For market stock carotene requirements have been halved, and for breeding stock they have been reduced by one-sixth. All vitamin D and riboflavin requirements have been raised. Pantothenic acid requirement for breeding stock has been added, as have choline and vitamin B₁₂ requirements for young pigs.

Data are included for the first time in this edition on essential amino-acid requirements for weanling pigs, and there is also a table giving the approximate amino-acid composition of some pig feeds. Much more information is given on requirements of certain trace minerals, and a new table of tentative quantitative recommendations for Cu, Fe, I and Mn has been added. There is a new paragraph giving a summary of experimental findings on the usefulness of dietary antibiotics for all classes of pigs, with data on rates of inclusion in the ration. The table of clinical signs of dietary deficiencies has been extended to include choline and vitamin B₁₂, and choline has been included in the table of composition of feeding-stuffs. The list of feedingstuffs in this second table has also been extended. Photographs have been added to show typical signs of calcium, pantothenic acid and lysine deficiencies.

CLAUSEN, H. and THOMSEN, R. N. 42. Beretning om sammenlignende forsøg med svin fra statsanerkendte avlscentre 1952-53. [42nd

Report on comparative tests with pigs from state recognised breeding centres 1952-53.] *Forsøgslab. København Beretn.* No. 273, 1954, pp. 141.

The work at 3 new pig testing stations is described. The pigs are individually fed on barley and skimmed milk with 1.5 g. cod liver oil daily, providing 3000 I.U. vitamin A and 300 I.U. vitamin D, and 5 to 10 g. daily of a mixture of 80 per cent. chalk and 20 per cent. salt. A table details the allowances of milk and barley at weights from 13 to 15 to 88 to 92 kg. Only best quality Danish barley is used. Its composition month by month is shown. The milk is sampled daily and analysed twice a month.

Points of interest from the report are: the distribution curves of measurements of backfat (p. 20) show the reduction both of mean thickness and of dispersion since 1926-27 and 1935-37. The present mean for Landrace test pigs is 3.43 cm.; the ideal is believed to be 3.25 which, from the distribution, will give the greatest number of pigs in Class 1. Since the thickness of backfat depends on genetic capacity to produce lean, on weight at slaughter and inversely on body length, selection should be for capacity to produce meat and for length. The target may easily be overshoot, but an additional 2 cm. to 95.5 cm. length might be safe.

Tables show the growth rates of Landrace and Yorkshire pigs from 1923-24 and mean feed consumption in feed units at intervals from 1909-10. Daily increase in weight has increased from 597 to 665 g. for Landrace and from 595 to 654 for Yorkshire. Feed consumption has decreased from 3.77 for Landrace and 3.89 for Yorkshire to 3.06 and 3.09 feed units per kg. weight gain.—I. Leitch.

BECKER, D. E. and TERRILL, S. W. Various carbohydrates in a semipurified diet for the growing pig. *Arch. Biochem. Biophys.*, 1954, 50, 399-403. [Dept. Animal Sci., Univ. Illinois, Urbana.]

During one experiment which began when the

N.A. and R., January 1955

pigs were 9 weeks old and lasted for 39 days, the diets contained 50 per cent. of either glucose, lactose, sucrose, dextrin or maize starch. Pigs with lactose in their diet ate less feed and grew more slowly than those on the other treatments ($P < 0.01$) but there was no statistically significant difference in feed required per kg. liveweight gain.

A second experiment began when the pigs were 16 weeks old and also lasted for 39 days. To the diet was added 6.25, 12.50, 25.00 and 50.50 per cent. lactose, and each level was given with and without an antibiotic supplement. Only the 50 per cent. level had a marked depressing effect on feed intake, growth rate and efficiency of feed conversion. Antibiotics tended to suppress these ill effects on feed intake and growth rate, but did not affect feed conversion efficiency. During both experiments moderate diarrhoea was associated with high levels of lactose in the diet.

A comparison of results previously obtained by 2 of the authors with those presented showed that the lactose tolerance of the pig decreases with age, but the ability to utilise sucrose increases with age.—I. A. M. Lucas.

BECKER, D. E., ULLREY, D. E., TERRILL, S. W. and NOTZOLD, R. A. Failure of the newborn pig to utilize dietary sucrose. *Science*, 1954, 120, 345-346. [Dept. Animal Sci., Univ. Illinois, Urbana.]

In continuation of work already reported (Abst. 3929, Vol. 24), 4 groups of newborn pigs were given, for 9 days, the same synthetic milk diet with D-glucose, sucrose, D-fructose or invert sugar constituting 57 per cent. of the dry matter. Survival and growth rates were best in the D-glucose and invert sugar groups; of 7 and 6 pigs, respectively, in them, 1 died in each group and the average weight gains by survivors over the period were 1.12 and 0.49 kg. In the sucrose and D-fructose groups each with 7 pigs, 6 and 5 died and for these groups the averages for weights at death or at termination of the experiment were 0.32 and 0.31 kg., respectively, less than the average initial weight. With either sucrose or D-fructose diarrhoea was severe after 18 hr. and became progressively worse; with invert sugar it was moderate and with glucose it did not occur.

It is concluded that the baby pig is unable to hydrolyse the glycosidic bond of sucrose because, it may be, of the absence of intestinal sucrase.

LEROY, A. M. Variation des besoins alimentaires des porcs en fonction de la saison. [Variation in feed requirements of pigs according to season.] *Ann. Zootech.*, 1953, 2, No. 1, 1-9. [Dept. Zootech., Inst. Nat. Agronom., Paris.]

Vol. 25, No. 1

This statistical study was made on the records of Large White pigs at the Bois-Corbon experimental station, and in particular of the weight changes and feed consumption of fattening pigs from 25 to 100 kg. in weight.

Summer and autumn were the best seasons for fattening pigs and winter the worst, but in the youngest animals, from 25 to 35 kg. in weight, summer was the worst time for growth. Pigs weighing more than 65 kg. obtained less benefit from the warm months than did those of 35 to 65 kg. Pigs weighing less than 55 kg. were more sensitive to the cold season than older animals. Less feed was required per kg. liveweight gain between June and November than between December and May. It is considered that the micro-climate of the piggery may have an important influence on the economics of production of fat pigs.—D. Duncan.

KRÜGER, L., BIEDERMANN, F. and PETZOLD, E. Zwei Jahre hessische Schweine-Mastleistungsprüfung auf dem Oberen Hardthof bei Giessen. [Two years of fattening tests with Hessian pigs at Upper Hardthof near Giessen.] *Der Tierzüchter*, 1953, No. 2.

Records before the war showed that, between the liveweights of 30 and 90, or 40 and 100 kg., pigs might eat anything from 2.8 to 6 kg. fattening ration per kg. weight increase. The saving in feedingstuffs that would be procured by using only the more efficient pigs would be enormous. Post-war litter testing at the Oberen Hardthof, the farm of the Animal Breeding College at Giessen, is briefly described. Up to 1944 the records show a range from 363 to 909 g. weight gain daily and from 2.86 to 5.76 kg. feed per kg. weight gain. Post-war the standard of performance for approved litters has been not more than 3.8 kg. of the prescribed ration per kg. weight gain from 40 to 110 kg. liveweight and a daily increase of at least 650 g. Of 49 groups tested, 28 attained that standard. The mean performance of this approved group, and the range for the whole lot of litters, were: feed, kg. per kg. weight gain, 3.53 and 2.94 to 4.22; daily weight gain 720 and 507 to 873 g.; age in days at 110 kg. 205 and 180 to 258.—I. Leitch.

BECKER, D. E., LASSITER, J. W., TERRILL, S. W. and NORTON, H. W. Levels of protein in

practical rations for the pig. *J. Animal Sci.*, 1954, 13, 611-621. [Univ. Illinois, Urbana.]

Three experiments are reported. In experiment 1, weanling Duroc pigs were fed from 42 to 100 lb. liveweight on maize, vitamin, mineral and antibiotic diets supplemented with solvent-extracted soya bean oilmeal (44.6 per cent. protein) or Menhaden fishmeal (62.5 per cent. protein) to bring the protein up to 10, 12, 14 and 16 per cent. From 100 to 200 lb. liveweight the pigs were re-randomised and fed on similar diets containing 10, 12 or 14 per cent. protein. Experiment 2 followed the same pattern except that before 100 lb. the levels of protein studied were 12, 14, 16 and 18 per cent. and after 100 lb. 8, 10 and 12 per cent. In both experiments an equalised feeding technique was used. In experiment 3, pigs were full-fed from 40 to 100 lb. on supplemented maize and soya bean oilmeal diets containing 10, 12, 14 and 16 per cent. protein.

For growth from 42 to 100 lb. liveweight there was no advantage in any experiment of raising the protein level of the maize and soya bean oilmeal diets above 14 per cent., but 16 per cent. protein was better than 14 per cent. in the maize and fishmeal diets. From 100 to 200 lb. liveweight the type of supplementary protein was without effect. In experiment 1, there was no significant difference between the 10, 12 and 14 per cent. protein levels, but in experiment 2 the difference in favour of 12 per cent. protein over 8 or 10 per cent. was significant.

It is stated in the discussion that lower total protein levels might be satisfactory when derived from low-protein maize and a higher proportion of soya bean oilmeal. It is suggested that tryptophan is the limiting amino-acid necessitating the slightly higher total protein percentage in maize and fishmeal diets before 100 lb. liveweight and also that the amino-acid requirements of the weanling pig are lower than is currently recognised. In the experiments reported the lysine, tryptophan and methionine content of the rations which supported satisfactory performance was 0.63, 0.13 and 0.23 per cent. from 40 to 100 lb. and 0.52, 0.10 and 0.21 per cent., respectively, from 100 to 200 lb.

TERRILL, S. W., BECKER, D. E., NORTON, H. W., WARDEN, W. K. and ADAMS, C. R. Some plant and animal sources of crude protein for weanling pigs fed in drylot. *J. Animal Sci.*, 1954, 13, 622-629. [Univ. Illinois, Urbana.]

In experiment 1, there was no advantage to pigs between 36 and 100 lb. liveweight of increasing the protein content of a diet of soya beans, maize, vitamins, minerals and antibiotic from 16 to 18 per cent. When a similar diet contained meat-and-bone scraps instead of soya bean, with the

total protein kept at 18 per cent., there was a significant advantage from additional supplementation with DL-tryptophan. There were significant differences between the growth rates of pigs on diets of maize, minerals, vitamins and antibiotic supplemented with a blend of 5 samples of extracted soya bean oilmeal, a new process-extracted soya bean oilmeal or a blend of 4 samples of meat-and-bone scraps. The average daily gains adjusted to equal feed consumption were 1.19, 1.09 and 0.96 lb., respectively.

In experiment 2, 16 pigs were fed individually on semi-purified diets containing about 11 per cent. crude protein derived from dried skimmed milk, blended soya bean oilmeal, new process-extracted soya bean oilmeal or blended meat-and-bone scraps. On the basis of rate of liveweight increase and efficiency of feed conversion there was no significant difference between the protein qualities of the soya bean meals, but the protein of dried skimmed milk was better than that of soya bean oilmeal, which was better than that of meat-and-bone scraps.—I. A. M. Lucas.

HIRONAKA, R. and BOWLAND, J. P. Antibiotic feed supplements in western Canadian swine ration. *Canad. J. Agric. Sci.*, 1954, 34, 343-352. [Dept. Animal Sci., Univ. Alberta, Edmonton.]

Two experiments are reported. In the first, 7 groups of 6 Yorkshire weanling pigs were each self-fed with one of the following supplements added to 1 lb. basal ration: (1) none, (2), (3) and (4) 9 mg. aureomycin hydrochloride to 75, 125 and 200 lb. liveweight, respectively, (5), (6) and (7) 1 mg. procaine penicillin to 75, 125 and 200 lb. liveweight, respectively. All pigs were slaughtered at 200 lb. From weaning to 75 lb., pigs receiving aureomycin grew significantly faster than both the controls and those receiving penicillin. From weaning to 125 lb. or to 200 lb. there was no significant difference in growth between treatments, but the fastest growth rates were in groups (3) and (4). Although in the early stages of growth efficiencies of feed conversion of some groups receiving antibiotics were better than for the controls, there was no significant difference between groups over the whole experimental period. Giving antibiotic supplements only to 75 or 125 lb. affected neither carcass grade nor score, but giving them to slaughter tended to reduce carcass length. The carcasses from all groups receiving antibiotics shrank significantly more during chilling than the controls.

In the second experiment all-vegetable protein rations containing 17, 15 or 13 per cent. crude protein were given to weanling pigs with and without 2 mg. procaine penicillin per lb. From 110 to 200 lb. liveweight these pigs all received a 13 per cent. protein ration without antibiotic.

N.A. and R., January 1955

There were 2 replicates of the experiment. In replicate A, all pigs receiving penicillin grew significantly faster than those on the basal rations, and this advantage was maintained from 110 to 200 lb. liveweight. The response to antibiotic increased with protein level, but feed efficiencies were not appreciably affected by antibiotic. In replicate B, penicillin did not improve liveweight gain or feed efficiency, and when antibiotic was removed from the diet after 110 lb. liveweight there was a check in the growth of pigs previously given the 15 and 13 per cent. protein levels.

In replicate A, but not in B, backfats were thicker and areas of the "eye of lean" were smaller in carcasses from antibiotic-fed pigs. In both replicates there was increased carcass shrinkage on cooling in the antibiotic groups. Differences in carcass quality between replicates may have been a reflection of the different growth responses obtained.—I. A. M. Lucas.

AMSCHLER, J. W. and WALASEK, E. Fütterungsversuche mit Antibiotika. Mastversuche normaler Schweine und Kümmerer mit Aureofac-2A unter Berücksichtigung der Freilandhaltung und verschiedener Stufen tierischen Eiweisses. [Feeding experiments with antibiotics. Fattening experiments with normal and unthrifty pigs with Aureofac-2A taking into account outside runs and level of animal protein (in rations).] *Bodenkultur*, 1953, 7, 239-250. [Inst. Tierzucht, Hochsch. Bodenkultur, Vienna.]

Two groups of pigs were selected from a lot of 100, aged 3 to 6 months, bought in open market, 32 "Kümmerer", weight 18 to 33 kg., average 25.0 kg., and 50 "normal" pigs, weight 21 to 47 kg., average 35.2 kg. They were similarly fed and managed except that the subnormal pigs had Aureofac-2A for the first 57 days, to supply per head daily 1.482 mg. aureomycin. During the first 27 days both groups had as part of their ration a silage of poorest quality. Of this the control group ate much more than the subnormal, had diarrhoea and put on no weight. Most of the advantage of the Aureofac group accumulated during this phase. In the second part of the experiment, 36 days, the groups were combined but weighed separately; Aureofac was omitted. There was no difference between the weight increases.

In a similar experiment 26 Kümmerer again had Aureofac and there were 44 controls without. For the first 57 days all had fishmeal, thereafter only plant protein. The Aureofac group had a slight advantage in the first stage; they overtook and passed the control group in the plant protein stage to finish at an average weight of about 90 kg. in 49 days. The controls took 76 days so that the

average daily gains were: Aureofac 696 g. and control 440 g.—I. Leitch.

1412

SHIRLEY, R. L., WALLACE, H. D. and DAVIS, G. K. Effect of dietary aureomycin and different levels of protein on several phosphorus and nitrogen compounds in hams. *J. Agric. Food Chem.*, 1954, 2, 830-832. [Dept. Animal Husb., Univ. Florida, Gainesville.]

Fifty-four pigs were divided into 6 groups and fed on maize and soya bean rations containing 14.3, 17.6 or 20.9 per cent. crude protein. Each protein level was given with and without aureomycin at the rate of 20 g. per 100 lb. feed. After slaughter at about 191 lb. liveweight the meat was separated from the skins and bones of hams from several pigs in each group, and was analysed for total solids, 4 nitrogen fractions and 4 phosphorus fractions. Neither protein level nor the presence of aureomycin significantly affected the concentrations of acid-soluble and nucleic P, nucleic acid and ammonia N, and total solids in the meat. Lipid P was significantly increased only when aureomycin was given with the 17.6 per cent. protein diet, and phosphoprotein P was significantly increased by aureomycin only when given with the 2 highest protein levels. The percentages of protein and phosphoprotein N in the hams were highest in the group on rations containing the largest amount of crude protein.

It is suggested that the interaction effect of protein and aureomycin on the lipid P might be associated with the greater backfat thickness of pigs given aureomycin, and that the dietary protein effects on phosphoprotein P and N point to phosphoprotein metabolism as determining the amount of total protein found in the hams.

1413

McKAY, W. M. The feeding of antibiotics to farm animals. *Brit. Vet. J.*, 1954, 110, 329-334. [Spillers, Ltd., London.]

Results are briefly given of extensive trials in different farms in Scotland, England, Wales and the Channel Islands with some 2000 pigs, on the value of giving antibiotics to pigs under different environmental and climatic conditions.

The regular provision of aureofac 2A from about 3 weeks of age up to 100 lb. liveweight gave better results at slaughter than its provision at several other times during that period.

The addition of an antibiotic containing appreciable amounts of vitamin B₁₂ to an all-vegetable ration gave growth results as good as those obtained on a ration containing fishmeal, and efficiency of feed conversion was improved. Antibiotic up to weaning at 8 weeks prevented a post-weaning check in growth.

The administration of aureomycin to pigs suffering from scours was curative, and mortality from paratyphoid infection was reduced by 50 per cent.

CHILDS, G. A. and CUTHBERTSON, W. F. J. The effect of procaine penicillin on the growth of weaned pigs. *J. Sci. Food Agric.*, 1954, 5, 330-335. [Glaxo Labs., Ltd., Greenford, Middlesex.]

The effect of procaine penicillin on the growth of pigs was tested at 6 farms in the United Kingdom under conditions typical of British pig rearing practice. The pigs were from home-reared litters and rations normally used at each farm were employed.

The average daily weight gain was 1.156 lb. for controls and 1.273 lb. for pigs receiving penicillin at the rate of 5 or 15 mg. per ton of feed, and there was no significant difference in the rate of gain at these levels. Feed efficiency was 4.08 and 3.70 lb. per lb. gain for the control and supplemented groups. It is suggested that a level of penicillin lower than 5 mg. per ton may prove satisfactory.

The results were in close agreement with those reported by the Agricultural Research Council (see Abst. 1324, Vol. 24).—J. S. Thomson.

1415

KROFF, D. H., PEARSON, A. M. and WALLACE, H. D. Observations on the use of waste beef fat in swine rations. *J. Animal Sci.*, 1954, 13, 630-637. [Dept. Animal Husb., Florida Agric. Exp. Stat., Gainesville.]

Four experiments covering 73 pigs are reported and, for all, the control rations were of maize, soya bean oilmeal and meat-and-bone scraps. In experiments 1 and 2 there were 2 dietary treatments, (1) a control and (2) a diet in which 10 per cent. of ground waste beef fat replaced some maize. In experiment 3 the diets were: (1) and (2) as in experiment 1; (3) control plus 10 per cent. beef fat plus 7 B vitamins and (4) hand-fed beef fat plus a self-fed protein supplement. In experiment 4, diets were (1) control; (2) as in experiment (3), diet 3; (3) control plus 10 per cent. beef fat plus 3 B vitamins and (4) control plus 15 per cent. beef fat plus 7 B vitamins. Pigs of average liveweight 115 to 120 lb. were used in experiments 1 and 2, and weanlings were used for experiments 3 and 4.

In the first 2 experiments, pigs given diets containing fat grew as fast as the controls and used slightly less feed per 100 lb. gain. In experiments 3 and 4 it was only when additional B vitamins were added to the diets containing fat that growth rates significantly faster than those of the controls were achieved. This may have indicated a vitamin deficiency in the control diet. Efficiency of feed

conversion was better in groups on diets containing fat, but the hand-feeding of fat and the self-feeding of protein supplement resulted in scouring and slow and inefficient growth. The inclusion of fat in the diet had no significant effect on the dressing percentages, carcass measurements or iodine numbers of depot fats, but animals hand-fed with fat and self-fed with protein supplement were longer and leaner and had lower dressing percentages. These effects may have been related to the slow growth of these pigs.—I. A. M. Lucas.

1416

ILANČIĆ, D., JEŽIĆ, J. and ŠMALCELJ, I. Djelovanje pivskog i pekarskog kvasca na stimulaciju tova starijih svinja. [The effect of brewer's and baker's yeasts on growth stimulation in fattening older pigs.] *Veterinaria*, 1953, 2, 288-298. English summary.

Pigs 12 to 15 months old received a basal ration of ground maize. In the first group the feed was moistened and fermented with baker's yeast. The second group received dry brewer's yeast. The third group was a control. Good results were recorded in the second group, 672 g. daily gain, good appetite and high feed utilisation. There was no difference between the control group and the group on moistened and fermented feed. This was possibly due to poor multiplication of yeasts in the moistened feed.—S. Pribičević (Yugoslavia).

1417

FÉVRIER, R., LEROY, A. M. and ROCHE, J. Influence du mode de séchage sur la valeur alimentaire de la levure de distillerie. [Effect of method of drying on the nutritive value of distiller's yeast.] *Ann. Zootech.*, 1952, 1, No. 4, 1-10. [Stat. Recherches Élevage, C.N.R.Z., Jouy-en-Josas.]

Yeasts grown in beet juice and on molasses were dried in 3 different ways: beet yeast emulsion was dried to powder in a current of air at 140° [presumably °C.]; emulsions of both kinds were dried on rollers at 130° for 10 sec., forming flakes; and both kinds were dried at 60° for 30 to 45 min. and slowly shaken, forming granules. The nutritive values of the dried products were compared in experiments on groups of 7 or 8 pigs with growing and fattening rations.

All beet yeasts gave better weight gains than the molasses yeasts, but the experimental conditions were not identical. The difference in value between the 3 beet yeasts was not significant, but the molasses yeast roller-dried at 130° was slightly inferior to that dried at the lower temperature. Such differences in growth as appeared were due to differences in feed consumption, which were greatest with the "atomised" beet yeast. The results are not considered to be conclusive.

CRAMPTON, E. W. and LLOYD, L. E. The use of malt sprouts in the bacon hog ration. *J. Animal Sci.*, 1954, 18, 638-647. [Fac. Agric., McGill Univ., Macdonald Coll., Que.]

In the hope of decreasing growth rate and thus improving carcase quality, malt sprouts were included as a source of fibre in rations for pigs self-fed from 115 to 200 lb. liveweight; but although the addition of 20, 30 and 40 per cent. wheat bran to a diet of barley plus protein and a mineral supplement did reduce rate of gain and improve carcase quality, the addition of 8, 12 and 16 per cent. malt sprouts resulted in stimulation of appetite and higher growth rates. When growth rates were adjusted to the test average daily feed intake they still increased with increasing level of malt sprouts, despite parallel increases in crude fibre content of the diet.

A second experiment planned to extend this observation was discontinued because of scour among the pigs, but there was a much lower incidence of scour among pigs fed on diets containing 12 per cent. malt sprouts than among pigs on the control diet or the control supplemented with 2 g. procaine penicillin and 3 mg. vitamin B₁₂ per ton.

The second experiment was later repeated with pigs from weaning to 200 lb. liveweight. Before 115 lb. liveweight 12 per cent. malt sprouts in the diet stimulated growth, but not so much as a supplement of 5 g. terramycin per ton of feed. When pigs were given the control diet, or the control supplemented with terramycin, before 115 lb., the inclusion of malt sprouts in the fattening diet produced no significant growth response from 115 to 200 lb. liveweight, an observation at variance with the first experiment. When pigs were given a diet containing both terramycin and sprouts before 115 lb., the removal of the sprouts from then on did not affect growth, but when pigs had received sprouts but no terramycin the removal of the sprouts from the fattening diet caused a decline in feed intakes and growth rates. There was therefore a similarity between the effects of malt sprouts and antibiotic, in pig rations. No dietary treatment in the second experiment influenced carcase grading.—I. A. M. Lucas.

LEROY, A. M. and ZELTER, S. Z. Recherches sur l'efficacité alimentaire des marcs de pomme fermiers. 3. Effet de la consommation d'un marc de pomme ensilé sur la croissance du porc. Incidences sur l'utilisation nutritive de la ration. [The feeding value of cider apple residues. 3. Effect of ensiled apple residue on the growth of pigs. Notes on the utilisation of

Vol. 25, No. 1

the nutrients in the ration.] *Ann. Zootech.*, 1954, 3, No. 2, 109-124. [Lab. Recherches Zootech., Inst. Nat. Agronom., Paris.]

See Abst. 5330, Vol. 24.

There were 4 groups of 20 pigs, half of them Large White and half Large White × Normandy crosses. The control rations were those used in the experimental piggery at Bois-Corbon, a relatively high-protein mixture to 60 kg. weight and one with less protein thereafter. It was provided to appetite. The first experimental group had 2 kg. apple silage, barley to appetite and 0.6 kg. of a high-protein mixture; the second had 2 kg. apple silage, 2 kg. steamed potato silage, barley to appetite and 0.6 kg. protein supplement; and the third had apple silage to appetite, barley to appetite and the same allowance of the protein mixture, which was of barley 25, meatmeal 10, fishmeal 7, distiller's yeast 5, groundnut cake 45 and salt mixture 8. A vitaminised oil provided 2500 I.U. vitamin A and 250 I.U. vitamin D₃ daily.

The rations were given mixed, but the pigs separated the parts and ate the concentrate part first, the potatoes second and the apple silage last. The group given apple silage to appetite increased its consumption to 3.28 kg. daily but at that level appetite suffered and barley had to be rationed to maintain apple silage at a high level. Apart from this effect on appetite, there was no sign of intolerance. In composition the rations were almost identical except for crude fibre, which was higher in proportion to the amount of apple silage eaten.

Rates of growth in the experimental groups with rationed apple silage and fibre contents of their rations of 8.9 and 9.1 per cent. (controls 6.1 and 5.2) were the same as or not significantly different from those of the corresponding control pigs. But the high-silage group, fibre 10 per cent., put on only 607 g. daily, or 89.3 per cent. of what the control pigs put on. This is interpreted to mean that the fibre is not responsible, but the physical nature of the apple residue.

Consumption of concentrates was reduced by 13 per cent. in the groups given apple silage and by 34 per cent. in that given both apple and potato. Quality of all carcasses was satisfactory.—I. Leitch.

1420

WHATLEY, J. A. (Jr.), GARD, D. I., WHITEMAN, J. V. and HILLIER, J. C. Meat-type hog production: influence of breeding and energy content of the ration on pork carcasses. *Oklahoma Agric. Exp. Stat. Bull.* No. B-398, May 1953, pp. 11. [Stillwater, Okla.]

Groups of 4 pigs were selected from each of 12 litters, which represented 7 different breeding lines. Each group was subdivided into 2 lots of two. Both lots were self-fed from weaning to 140 lb.

liveweight on identical high-energy rations. From 140 to 225 lb. liveweight one lot was self-fed on a diet containing 1.52 therms metabolisable energy per lb. and the other lot was self-fed on a more fibrous diet containing 1.42 therms metabolisable energy per lb. All pigs were taken off feed for 20 to 24 hr. before slaughter.

From 140 to 225 lb., pigs on the high-energy ration gained 1.96 lb. and those on the low-energy ration 1.38 lb. daily. There were also significant differences in rate of gain between breed groups. No data are given for efficiency of feed conversion between 140 and 225 lb., but from weaning to slaughter pigs on the high-energy ration ate 357 lb. feed per 100 lb. gain and those on the low-energy ration ate 433 lb. Part of this difference was attributed to waste of the unpalatable low-energy diet. For feed conversion efficiency differences among breeds were not significant.

Pigs on the low-energy ration from 140 to 225 lb. produced the longer, meatier and leaner carcasses, but at slaughter their intestinal tract was 2 lb. heavier than that of pigs on the high-energy ration and they dressed out 2 per cent. lower. Gilts produced leaner carcasses than castrated males and had a higher percentage of lean cuts but a slightly lower dressing percentage.

Although there was no significant difference in length or dressing percentage between breed groups there were significant differences in fat measurements and yields of lean cuts. It is concluded that it is more economical and easier to produce

pigs of meat type by proper breeding than by modifying the diet.—I. A. M. Lucas.

1421

FÉVRIER, R. Premières observations sur le comportement alimentaire des porcs. [Food behaviour in pigs.] *Ann. Zootech.*, 1952, 1, No. 3, 63-69. [Stat. Recherches Élevage, C.N.R.Z., Jouy-en-Josas.]

Eight groups of pigs weighing between 40 and 85 kg., accustomed to a standard ration, had their diet suddenly changed to another of similar composition but prepared from different materials. Feed consumption was estimated for 4 days after the change and compared with consumption before the change and after the return to the original diet. Average consumption during the period of change was 2.23 kg. per day as compared with 2.96 kg. on the average before the change and after reversion to the original diet. Consumption by pigs weighing 60 kg. was least affected by the change, but for pigs weighing over or under this amount there was a graded reduction in consumption.—J. S. Thomson.

GOATS, RABBITS AND OTHER MAMMALS

1423

NATIONAL RESEARCH COUNCIL, U.S.A. Nutrient requirements for domestic animals. 8. Nutrient requirements for dogs. Publ. No. 300, December 1953, pp. iii + 30.

Requirements are complicated by variety of size, body conformation, hair coat, activity and disposition. From a review of the literature it is suggested that the dry type diet should contain 8 to 10 per cent. moisture, 18 per cent. protein for growth or 13.5 per cent. for maintenance, up to 70 per cent. carbohydrate for growth or 75 per cent. for maintenance, 4.5 per cent. fat, 1.0 per cent. Ca, 0.8 per cent. P (the last 2 values being minimum), 1.4 per cent. NaCl and 0.8 per cent. K. Suggested amounts of nutrients required per lb. bodyweight daily for adult maintenance and for growth are: energy 50 and 100 Cal. for 5-lb. dogs, 42 and 84 Cal. for 10-lb. dogs, 35 and 70 Cal. for 15-lb. dogs, 32 and 64 Cal. for 30-lb. dogs and 31 and 62 Cal. for dogs of 50 lb. or over; protein 1.7 and 4.5 g.; carbohydrate 8.0 and 14.7 g.; fat 0.6 and 1.1 g.; Ca 120 and 240 mg.; P 100 and 200

mg.; Fe 0.6 and 0.6 mg.; Cu 0.075 and 0.075 mg.; NaCl 170 and 200 mg.; K 100 and 240 mg.; Mg 5 and 16 mg.; Mn 0.05 and 0.1 mg.; Zn 0.05 and 0.19 mg.; I 0.015 and 0.015 mg.; vitamin A 45 and 90 I.U.; vitamin D 3 and 9 I.U.; vitamin E 1 mg. for growth; vitamin B₁₂ 0.25 and 0.5 µg.; vitamin B₁ 0.008 and 0.015 mg.; vitamin B₆ 0.02 and 0.04 mg.; pantothenic acid 0.025 and 0.045 mg.; nicotinic acid 0.11 and 0.18 mg. and choline 15 and 25 mg. Further tables show estimated food intakes required by dogs of different sizes, energy and feed requirements for dogs of different weights, minimum protein requirements for N equilibrium and amino-acids required to maintain normal plasma protein regeneration.

The amounts listed above would appear to be adequate, but there are frequently no data to show whether they are as low as they might be.

J. S. Thomson.

1424

NATIONAL RESEARCH COUNCIL, U.S.A. Nutrient requirements for domestic animals. 7. Nutrient requirements for foxes and minks. Publ.

N.A. and R., January 1955

No. 296, November 1953, pp. 30. Price \$0.50.

The literature has been reviewed and tables of requirements have been compiled which are subject to revision in the light of further experimental work.

For male foxes the daily requirements for growth at 7, 19 and 35 weeks are given as: protein 15, 53, 28 g., vitamin A 101, 367, 257 I.U., vitamin B₁ 0.06, 0.24, 0.16 mg., riboflavin 0.12, 1.7, 1.2 mg., nicotinic acid 0.6, 2.1, 1.5 mg., vitamin B₆ 0.06, 0.24, 0.16 mg., folic acid 0.012, 0.042, 0.030 mg., Ca 0.4, 1.3, 0.9 g., P 0.4, 1.3, 0.9 g.

For male mink corresponding data at 7, 19 and 31 weeks are: protein 10, 12, 13 g., vitamin A 78, 133, 140 I.U., vitamin B₁ 0.05, 0.08, 0.09 mg., riboflavin 0.09, 0.15, 0.16 mg., pantothenic acid 0.36, 0.61, 0.65 mg., nicotinic acid 0.45, 0.76, 0.81 mg., vitamin B₆ 0.05, 0.08, 0.09 mg., folic acid 0.009, 0.015, 0.016 mg., Ca 0.18, 0.32, 0.36 g., P 0.18, 0.32, 0.36 g.

Allowances for females of the species were somewhat less. Tables of composition of feedingstuffs are appended along with basic formulae for fox and mink diets.—J. S. Thomson.

KAEMMERER, K. Messungen an Ziegenböcken. [Measurements of buck goats.] *Ztschr. Tierzücht. Züchtungsbiol.*, 1954, 63, 71–86. [Inst. Anat. Haustiere, Univ. Bonn.]

1426

GEORGIDZE, V. K. Opyt kormleniya mekhovykh serebristo-chernykh lisitz po umen'shennym normam. [The feeding of silver foxes by reducing the standard amount of ration.] *Karakul. Zverovodstvo*, 1953, 6, No. 6, 42–45. [Bakurian Animal-Sovkhov.]

Feeding fox cubs on reduced rations hastened the maturity of the fur and improved the skins. This reduction to near starvation level caused the animals to shiver and become weak, and they should be transferred to a suitable diet under veterinary supervision.

The rations were reduced from the middle of September from a daily average of 600 Cal. to 350 Cal., and were further reduced in November to 300 Cal. per head, the control group receiving 600 Cal. during the corresponding period in September and 500 Cal. in October and November.

Underfeeding diminishes the layer of fat under the skin and the increasing cold stimulates the growth of fur. The more rapid maturing of the fur diminishes the number of defects in the skin and improves the colour of the fur.—H. Scherbatoff.

1427

RYASHCHENKO, L. P. Kormovye ratziony dlya tyelay pyatnistykh oleney. [Rations for spotted

Vol. 25, No. 1

deer calves.] *Karakul. Zverovodstvo*, 1953, 6, No. 5, 46–48. [Supporting Point of VNILZO.]

The usual daily amounts given to deer calves during the winter are 1 kg. coarse fodder, 0.3 kg. succulent fodder and 0.5 kg. concentrates. When separated from their dams they are generally given larger rations of both concentrates and succulent fodder, up to 1 kg. of concentrates per head. In order to check the validity of these methods of feeding an experiment was staged with 3 groups of 15 calves, with a preliminary preparation period from 6 December to 19 January and the main period from 20 January to 8 May.

The first group received up to 1.1 kg. mountain hay and 0.64 to 0.74 kg. concentrates per head daily; the second group up to 0.84 kg. hay, 0.15 kg. lespedeza leaves, 0.53 to 0.64 kg. concentrates; the third group up to 0.85 kg. hay, 0.05 to 0.15 kg. lespedeza leaves, 0.53 to 0.75 kg. fodder beet and 0.51 to 0.53 kg. concentrates. The nutrient values for the first group were 0.91 feed unit and 0.11 to 0.13 kg. digestible protein, the second group 0.88 to 0.95 feed unit and 0.12 kg. digestible protein and the third group 0.87 to 0.93 feed unit and 0.10 to 0.11 kg. digestible protein per head. The nutrient values were estimated for the part of the ration eaten.

In the third group the increase in weight was 27.3 per cent. greater than in the first, although the third group was receiving 23.5 per cent. less concentrates than the first group. In the males of the second and third groups development of the horns was better than in the first group. Increase in weight both during the winter and when at pasture was progressively better in the second and third groups, the least increase being in the first group.—H. Scherbatoff.

1428

GUSEV, V. M. Materialy po pitaniyu solongoya (Kolonoos Altaica Pall.) v del'te r. Ili. [Materials for the nutrition of *Kolonocus altaica* Pall. in the delta of the river Ili.] *Zool. Zh.*, 1953, 32, 539–548. [Vses. Nauch.-Issled. Inst. Ohlot. Prom. i Lab. Minzdrava SSSR.]

The basic food of the alpine weasel, *Kolonocus* [now *Mustela*] *altaica*, in the delta of the Ili river during all seasons is rodents of the mouse family, the amount varying with the season from 58 to 81 per cent. of food eaten; the next in order of importance is small birds, particularly during autumn and spring, when they form about 14 per cent. of the food, and fish in winter. Other foods eaten are shrews, sand hare, pheasants' or other birds' eggs, and insects, but these are of secondary importance. At times when, as the result of competition from other predators, there are not

enough mice, *Kolonocis* is compelled in the autumn to eat, up to 9 per cent. of its total food, fish, which it usually does not touch at this season, and in winter to eat 29 per cent. fish and to supplement this with other food normally of secondary importance. Compared with males the females

show a preference for larger animals, e.g., water rats instead of mice. Because it destroys disease carriers *Kolonocis* serves a useful purpose. Cases of its attacking valuable animals are exceptional and do not justify its being killed.—W. Hughes.

1430

NATIONAL RESEARCH COUNCIL, U.S.A. Nutrient requirements for domestic animals. 1. Nutrient requirements for poultry. Publ. No. 301, revised January 1954, pp. 27. Price \$0.50.

This new edition adheres to the pattern previously used in these publications. Nutrient requirements are, however, now presented without any "margin of safety" to allow for losses during the preparation and storage of mixed rations. It is considered that individual manufacturers can best determine margins suitable for their own particular conditions.

Estimates for folic acid requirements have now been included. For starting chicks, laying hens and breeding hens these are 0.25, 0.11 and 0.16 mg., respectively, per lb. feed. In arriving at these estimates more account has been taken of experiments in which starch and not sucrose has formed the main dietary carbohydrate; with the latter, requirements are higher.

A tentative figure of 0.004 mg. per lb. is given as an allowance of vitamin B₁₂ in a chick starting ration, but it is emphasised that the chick's requirement of this vitamin depends to a great extent on the diet received by the breeding flock, and on the other components of the chick ration.

Figures are also included for the amino-acid requirements of laying hens and for the total feed requirements of laying hens differing in bodyweight and level of egg production; for example, the daily requirement of a 4½-lb. bird laying 200 eggs per year is given as approximately 4 oz.

K. J. Carpenter.

1431

FISHER, H. and SCOTT, H. M. The essential amino acid requirements of chicks as related to their proportional occurrence in the fat-free carcass.

Arch. Biochem. Biophys., 1954, 51, 517-519. [Dept. Animal Sci., Illinois Agric. Exp. Stat., Urbana.]

From data reported elsewhere in the literature, for many of the essential amino-acids the requirement of the chick as a percentage of its ration (*y*) and its concentration in the body as a percentage of a 4-week-old carcass (*x*), closely fit the equation $y = 0.256 - 0.034x - 0.027x^2$.

The usually accepted figures for methionine and lysine are not in agreement with this, but for each a figure has been reported by other workers which is in close agreement. The only other amino-acid which is off the curve to a greater extent than could be explained by possible experimental error is phenylalanine, but there is some confusion about the activity of the D-isomer present in the samples used to obtain the original data.—K. J. Carpenter.

BALDINI, J. T., ROSENBERG, H. R. and WADDELL, J. The protein requirement of the turkey poult. *Poultry Sci.*, 1954, 33, 539-543. [Stine Lab., Grasselli Chem. Dept., E.I. du Pont de Nemours and Co., Inc., Newark, Del.]

Groups of 10-day-old Jersey Buff turkey poults were housed in batteries and given their all-mash rations, containing 0.2 per cent. DL-methionine, to appetite. In experiment 1, 2 basal rations of maize and soya bean oilmeal with alfalfa meal containing 20 and 28 per cent. protein, respectively, were given for the 4-week experimental period. Supplements of 0.30 per cent. L-lysine hydrochloride were given with the 20 per cent. protein ration. This addition improved chick growth, total feed efficiency and protein utilisation.

Experiment 2 was of factorial design with variables of 0.3 per cent. L-lysine hydrochloride, 3 per cent. condensed fish solubles and 1 per cent. complete vitamin concentrate as supplements to the 20 per cent. protein basal ration; a 28 per cent. protein ration was included as a control. The lysine supplement significantly improved growth and feed efficiency during the 3-week experimental period. The increase due to condensed fish solubles approached significance at the 5 per cent. level but that due to the vitamin concentrate was not significant.

N.A. and R., January 1955

Male poultz only were used in experiment 3. The variables were 0.2 per cent. DL-methionine, 0.3 per cent. L-lysine hydrochloride, 220 units procaine penicillin G per 100 g. feed and 3 per cent. condensed fish solubles with the 20 and 28 per cent. protein basal rations. The methionine supplement improved growth by 11 and 6 per cent., respectively. Improvements in growth and feed efficiency due to lysine and condensed fish solubles were significant at a 5 per cent. level and were additive, but the penicillin supplement had no effect on growth and only a slight positive effect on feed efficiency. Protein was most efficiently utilised from the low-protein rations, and utilisation was improved by the addition of lysine and methionine.—M. J. Head.

1433

SMITH, A. H., WILSON, W. O. and PACE, N. **The effect of high altitude on the growth of turkeys.** *Growth*, 1954, 18, 27-35. [Dept. Poultry Husb., Univ. California, Davis.]

1434

BLAYLOCK, L. G., HUNT, J. R., ZIEGLER, F., PATTERSON, E. B. and STADELMAN, W. J. **The effect of energy level of the diet on growth, feed efficiency and degree of fattening of turkeys.** *Poultry Sci.*, 1954, 33, 864-866. [Dept. Poultry Sci., Washington State Coll., Pullman.]

Duplicate groups of 50 male and female 8-week-old Broad Bronze turkeys were given the following rations: (1) high-energy pellets with whole maize, (2) high-energy pellets with whole barley or (3) low-energy pellets with whole maize. The high-energy pellets consisted mainly of maize and soya bean oilmeal and supplied 96.3 therms per 100 lb. feed, 20 per cent. protein and 2.5 per cent. fibre; the low-energy pellets were of mixed grain supplying 67.7 therms per 100 lb., 20 per cent. protein and 7.2 per cent. fibre. The energy value of maize is given as 114 and of barley as 81 therms per 100 lb. There was no difference between groups in liveweight but the greatest feed efficiency was obtained in both toms and hens on ration (1) and the least on ration (3). After dressing, there was no difference on a quality basis between the carcasses of hens from the 3 groups, but the carcasses of toms from group 3 were of poorer quality than those from the other 2 groups. The birds in groups 2 and 3 tended to decrease their fibre intake by selecting different ratios of grain to pellet.—M. J. Head.

1435

CARVER, D. S. and JOHNSON, E. L. **Further studies of the unidentified chick growth factors in unsaturated fats.** *Poultry Sci.*, 1954, 33, Vol. 25, No. 1

543-548. [Dept. Poultry Husb., Iowa State Coll., Ames.]

In a series of chick growth trials materials were tested as supplements to a basal ration of "Dracket industrial protein-220" 25, DL-methionine 0.64, choline chloride 0.15, minerals 5.5, cellulose 5, crystalline vitamins (in at least three times the allowances usually recommended) and dextrose to 100.

Duplicate groups, each of 10 chicks, fed to 2 weeks of age on the basal ration alone had a mean weight of 90 g., as did groups receiving the same ration with a supplement of the known fat-soluble vitamins. Groups receiving 2 per cent. of wheat germ oil or 1 per cent. of an oleic acid concentrate as supplements finished with mean weights of 102 and 100 g., respectively.

In further trials growth on the basal ration alone varied very much from one experiment to another, but there was a consistent response to the addition of maize oil, soya bean oil, wheat germ oil, an oleic acid concentrate or a pork liver residue, and to both the saponifiable and the non-saponifiable fraction of cottonseed oil. Commercially hydrogenated soya bean oil and butter showed little growth-stimulating activity. Responses to methyl linoleate, methyl linolenate and methyl oleate were inconsistent. The addition of 5 per cent. of lard to the basal ration depressed growth, and mortality was high.

Striking differences were noted in the fat and protein content of the carcasses between the chicks receiving growth-stimulating supplements and those receiving the basal ration alone.

K. J. Carpenter.

1436

FOX, T. W. and BOHREN, B. B. **An analysis of feed efficiency among breeds of chickens and its relationship to rate of growth.** *Poultry Sci.*, 1954, 33, 549-561. [Purdue Univ., Lafayette, Ind.]

In each of a series of 4 trials, 4 breeds of chicks were caged individually from 4 weeks of age and fed on a commercial broiler ration for 6 weeks; altogether 384 birds were used.

The New Hampshire birds had the heaviest mean finishing weight and also the highest feed conversion efficiency, 0.351; the White Leghorns were the lightest and had the lowest feed conversion efficiency, 0.297; the Dark Cornish and Dominant Whites were intermediate. Within each breed the males were heavier than the females and also had the higher efficiency of feed conversion; finally, regression analyses for each breed and sex showed a close positive correlation between feed conversion efficiency and average bodyweight over the experimental period.

On the basis of these and further statistical

analyses it is concluded that there is little justification for breeders of birds intended for meat production to practice selection on the basis of economy in feed conversion in addition to the simpler criterion of rapid early growth.—K. J. Carpenter.

FANGAUF, R. and BARLÖWEN, G. v. Dorschlebermehl im Kükenfutter. [Cod liver meal in chick rations.] *Arch. Geflügelk.*, 1954, 18, 203-205. [Lehr-Versuchsanst. Kleintierzucht, Kiel, Steenbek.] English summary.

Cod liver meal is used less in Germany than in some other countries because of its price. Some of it is of poor quality and when it contains much free fatty acid it may be poisonous to poultry. A sample of such meal contained 25.5 to 28.3 per cent. crude fat and 13 to 14 per cent. free fatty acids. Two groups of 30 New Hampshire day-old chicks were given a normal mixed ration with 5 per cent. of a liver meal of low fat content or of that described above. At the age of 4 weeks the chicks had eaten 414.3 g. (high fat) or 481.1 g. (low fat) food; weighed 187.1 g. and 244.8 g., and ate, per 100 g. weight increase, 198 g. or 164 g.

I. Leitch.

1438

FANGAUF, R. Die Anwendung von Ölkuchen-Extraktionsschrot im Kükenfutter. [Use of extracted oilcake meal in chick rations.] *Arch. Geflügelk.*, 1954, 18, 237-241. [Lehr-Versuchsanst. Kleintierzucht, Kiel, Steenbek.] English and French summaries.

Eight-week experiments on day-old chicks showed that waste meals from coconut, palm kernel and earlnut were as valuable as soya bean extracted meal, when used in the proportion of 8 per cent. in a ration which contained 8 per cent. of cod fishmeal. The results obtained with rapeseed meal were somewhat doubtful, and when 8 per cent. of linseed or cottonseed meal was given, the experiments had to be discontinued after 4 weeks, because of the severe losses of birds. A table is given showing the maximum quantities of vegetable protein substances recommended for the rations of chicks and laying hens.

M. B. Richards.

1439

FANGAUF, R. and BARLÖWEN, G. v. Mohnsaatmehl im Kükenfutter. [Poppy seed meal in chick rations.] *Arch. Geflügelk.*, 1954, 18, 205-207. [Lehr-Versuchsanst. Kleintierzucht, Kiel, Steenbek.] English summary.

Three groups each of 30 New Hampshire day-old chicks were given a normal mixed ration including 15 per cent. oatmeal, or 10 per cent. oatmeal and 5 per cent. poppy seed meal or 5 per cent. oatmeal and 10 per cent. poppy seed. The poppy seed meal contained per cent.: water 5.42, crude protein

17.63, ether extract 42.42, crude fibre 8.80, N-free extract 18.43 and ash 7.30. Free fatty acids were estimated at 4.97 per cent. as oleic acid. The results at 4 weeks were: without poppy seed, feed consumed 460.3 g.; bodyweight 238.9 g.; total nutrients, g. per 100 g. increase, 158; with 5 per cent. poppy meal, in the same order, 430.8 g., 223.6 g. and 167; with 10 per cent. poppy meal 431.8, 217.9 and 180. The difference in rate of growth arose only in the fourth week and there was no obvious harm done by either the fatty acids or the opium in the poppy seed meal.—I. Leitch.

1440

COWLISHAW, S. J., EYLES, D. E., RAYMOND, W. F. and TILLEY, J. M. A. Nutritive value of lucerne protein concentrates, fed with and without cholesterol. *Nature*, 1954, 174, 227-228. [Grassland Res. Inst., Hurley, Berkshire.]

Tests were made with a protein concentrate prepared by heat precipitation from alfalfa juice. Groups of 12 chickens were reared from hatching to 14 days on a low-protein ration and then received the test rations for another 14 days.

The gross protein values of alfalfa protein meal with 48.4 per cent. crude protein and of alfalfa and grass protein with 42.8 per cent. were 57 and 67, respectively, taking casein as 100. The addition of 0.3 per cent. cholesterol raised the values to 74 and 70. Alfalfa protein rations appeared to be less palatable than the casein ration.—D. Duncan.

1441

WILGUS, H. S. and MADSEN, I. L. The effect of alfalfa meal on early growth of chicks. *Poultry Sci.*, 1954, 33, 448-459. [Colorado Agric. Exp. Stat., Fort Collins.]

In this experiment groups of 25 New Hampshire chicks were given the experimental rations at 2 weeks of age for 4 weeks. In general, a high-energy maize and soya bean oilmeal ration was used as a basal feed. A difference of 10 per cent. in group chick weights was considered significant.

The effect on growth rate of 100 different samples of alfalfa meal was determined when it was included in the ration at a 10 per cent. level. The history of nearly all samples was known and nearly all came within the 17 per cent. protein class. Three samples of sun-cured meal depressed growth rate to below 70 per cent. of the control; 20 per cent. of the meals depressed growth more than 10 per cent. and a further 27 per cent. depressed growth by less than 10 per cent.; the remainder, 53 per cent., had no effect. The average growth rate when the 3 sun-cured meals were included was 92 per cent. of that of the control group, and 93.5 per cent. for the 100 dehydrated meals. The chick growth rates with

N.A. and E., January 1955

each cutting relative to the control group were 94.5 for the first cut, 94 for the second, 90 for the third, 95.5 for the fourth and 99.5 per cent. for the fifth. There was no relation between growth depression and digestibility. The meals giving the greatest growth depression were low in carotene. It was not believed that the slight differences in mineral content of the meals had any effect on their value for growth; nor was it considered that the depression of growth was due to the fibre content, since a slightly greater amount of cellulose fibre had no ill effect. The possible effects of weed contaminants or residues of spray chemicals were eliminated. Fine grinding compared with grinding to a granular consistency increased the growth-depressing effect of the meal, but this could be obviated by damping the fine meal with molasses. It was found that the growth-depressing substance was destroyed to a considerable extent by prolonged soaking in hot water, but it was resistant to autoclaving at 150° C. for 20 min. and was insoluble in acetone.—M. J. Head.

1442

ROSENBERG, M. M. Napier grass (*Pennisetum purpureum*) meal, a substitute for alfalfa meal in chick starter rations. *Poultry Sci.*, 1954, **33**, 803-809. [Dept. Poultry Husb., Coll. Agric., Univ. Hawaii, Honolulu.]

Napier grass cut at intervals of 3 to 14 weeks was dried at 110° F. for 72 to 96 hr. and milled through a 1/16-in. sieve. It was included at a 5 per cent. level in the rations of day-old New Hampshire chicks for a 21-day experimental period. Herbage, cut 3 to 10 weeks after the previous cut, replaced 5 per cent. alfalfa in the ration, and promoted as good growth as the alfalfa control. The amount of feed required per g. gain was from 1.93 to 2.0 g., compared with 2.01 g. for the alfalfa control. Rations containing 5 per cent. Napier grass meal from 11- to 14-week-old herbage were more variable than rations containing younger material in their effect on growth, but with all growth was similar to that on alfalfa. The inclusion of either alfalfa or Napier grass in the basal ration was shown to be essential.

M. J. Head.

1443

MORGAN, C. L. and WILLIMON, C. P. Cottonseed meal prepared by different methods for broiler rations. *Poultry Sci.*, 1954, **33**, 528-532. [Poultry Dept., S. Carolina Agric. Exp. Stat., Clemson.]

The 3 cottonseed meals used were a screw-press meal, 42 per cent. protein and 3.6 per cent. fat, a gossypol-free solvent meal, 41 per cent. protein and 1.6 per cent. fat, and a hydraulic meal, 41.6 per cent. protein and 8.3 per cent. fat; the control soya bean meal was a solvent-extracted product,

45.6 per cent. protein and 1.0 per cent. fat. The basal rations contained 21 per cent. protein and were of maize and oilmeal with 2 per cent. fishmeal and 2 per cent. dried whey, minerals and vitamins. The rations were given for 10 weeks to duplicate groups of 20 day-old New Hampshire chicks in wire-floored batteries. Substitution for about half the soya bean meal of any of the cottonseed meals did not affect growth. Only the gossypol-free cottonseed meal when given as the main source of protein produced growth equal to soya bean meal alone; the other 2 cottonseed meals gave significantly poorer growth. Mortality was not related to the ration. The feed efficiency of birds receiving cottonseed meals was satisfactory but not so high as that of birds receiving only soya bean meal.—M. J. Head.

1444

HEYWANG, B. W. and BIRD, H. R. Egg production, diet consumption, and live weight in relation to the free gossypol content of the diet. *Poultry Sci.*, 1954, **33**, 851-854. [Agric. Res. Serv., U.S. Dept. Agric., Bur. Animal Indust., Glendale, Ariz.]

Seven groups of 25 White Leghorn pullets were fed on all-vegetable rations containing 25 per cent. soya bean meal and yellow maize meal in which raw decorticated cottonseed meal was included to give contents of "free" gossypol ranging from 0.008 to 0.033 per cent. EBBELL, H. Weitere Untersuchungen über den Einfluss eines Terramycin-Produktes auf das Kükenwachstum. [Effect of a terramycin product on the growth of chicks.] *Arch. Geflügelk.*, 1954, **18**, 184-196. [Ovomaltine Farm, Oberwangen, Berne.] English summary.

Addition of 0.1 per cent. of a terramycin and vitamin B₁₂ supplement to the basal ration of chicks had no definite effect on their growth, or on efficiency of feed utilisation, whether it was given for the first 10 weeks, for the first 6 weeks, or from the sixth or the tenth week onwards. The cause

analyses it is concluded that there is little justification for breeders of birds intended for meat production to practice selection on the basis of economy in feed conversion in addition to the simpler criterion of rapid early growth.—K. J. Carpenter.

1437

FANGAUF, R. and BARLÖWEN, G. v. Dorschlebermehl im Kükenfutter. [Cod liver meal in chick rations.] *Arch. Geflügelk.*, 1954, 18, 203-205. [Lehr-Versuchsanst. Kleintierzucht, Kiel, Steenbek.] English summary.

Cod liver meal is used less in Germany than in some other countries because of its price. Some of it is of poor quality and when it contains much free fatty acid it may be poisonous to poultry. A sample of such meal contained 25.5 to 28.3 per cent. crude fat and 13 to 14 per cent. free fatty acids. Two groups of 30 New Hampshire day-old chicks were given a normal mixed ration with 5 per cent. of a liver meal of low fat content or of that described above. At the age of 4 weeks the chicks had eaten 414.3 g. (high fat) or 481.1 g. (low fat) food; weighed 187.1 g. and 244.8 g., and ate, per 100 g. weight increase, 198 g. or 164 g.

I. Leitch.

1438

FANGAUF, R. Die Anwendung von Ölkuchen-Extraktionsschrot im Kükenfutter. [Use of extracted oilcake meal in chick rations.] *Arch. Geflügelk.*, 1954, 18, 237-241. [Lehr-Versuchsanst. Kleintierzucht, Kiel, Steenbek.] English and French summaries.

Eight-week experiments on day-old chicks showed that waste meals from coconut, palm kernel and earthenut were as valuable as soya bean extracted meal, when used in the proportion of 8 per cent. in a ration which contained 8 per cent. of cod fishmeal. The results obtained with rapeseed meal were somewhat doubtful, and when 8 per cent. of linseed or cottonseed meal was given, the experiments had to be discontinued after 4 weeks, because of the severe losses of birds. A table is given showing the maximum quantities of vegetable protein substances recommended for the rations of chicks and laying hens.

M. B. Richards.

1439

FANGAUF, R. and BARLÖWEN, G. v. Mohnsaatmehl im Kükenfutter. [Poppy seed meal in chick rations.] *Arch. Geflügelk.*, 1954, 18, 205-207. [Lehr-Versuchsanst. Kleintierzucht, Kiel, Steenbek.] English summary.

Three groups each of 30 New Hampshire day-old chicks were given a normal mixed ration including 15 per cent. oatmeal, or 10 per cent. oatmeal and 5 per cent. poppy seed meal or 5 per cent. oatmeal and 10 per cent. poppy seed. The poppy seed meal contained per cent.: water 5.42, crude protein

17.63, ether extract 42.42, crude fibre 8.80, N-free extract 18.43 and ash 7.30. Free fatty acids were estimated at 4.97 per cent. as oleic acid. The results at 4 weeks were: without poppy seed, feed consumed 460.3 g.; bodyweight 238.9 g.; total nutrients, g. per 100 g. increase, 158; with 5 per cent. poppy meal, in the same order, 430.8 g., 223.6 g. and 167; with 10 per cent. poppy meal 431.8, 217.9 and 180. The difference in rate of growth arose only in the fourth week and there was no obvious harm done by either the fatty acids or the opium in the poppy seed meal.—I. Leitch.

HILL, C. H. and KELLY, J. W. **The effect of fish meal on the response of chicks to high levels of penicillin.** *Poultry Sci.*, 1954, **33**, 657-658. [Dept. Poultry Sci., N. Carolina State Coll., Raleigh.]

Six groups, each of 30 chicks, were fed from day-old to 4 weeks of age in battery cages where the room and equipment had recently been cleaned, steamed and fumigated.

The control ration consisted of soya bean meal 47, methionine 0.3, minerals 4.5, vitamins, and maize meal to 100. The groups that received this ration alone or supplemented with 9 or 90 p.p.m. of procaine penicillin finished with mean weights of 404, 385 and 398 g. Parallel groups receiving similar rations, but with 5 per cent. of fishmeal, added at the expense of soya bean meal and maize meal so as to keep the total protein content of the diets constant, finished with mean weights of 389, 398 and 420 g., respectively.

SLINGER, S. J. and PEPPER, W. F. **Effect of penicillin on the growth and feed consumption of turkey poults.** *Poultry Sci.*, 1954, **33**, 746-753. [Dept. Poultry Husb., Ontario Agric. Coll., Guelph.]

Broad Breasted Bronze poults were caged in groups of 40 and fed from day-old to 28 days of age on a ration made up of fishmeal 2, meatmeal 2, soya bean oilmeal 43, alfalfa meal 3, minerals 4, soya bean oil 1, yellow maize meal 15, oat groats 5, methionine, a vitamin mixture (including vitamin B₁₂) and ground wheat to 100. At 28 days of age a group receiving this ration to appetite had a mean weight of 471 g., and a similar group that had received a dietary supplement of 15 p.p.m. procaine penicillin G a mean weight of 533 g. Two further groups that received the ration alone or with a penicillin supplement each were given a daily weight of their diet equal to that eaten by the non-supplemented "ad libitum" group on the previous day, and finished with mean weights of 446 and 452 g., respectively. Feed to gain ratios for the 4 groups were 1.76, 1.66, 1.74 and 1.71. Similar results were obtained in a second trial of similar design.

From analysis of "daily feed consumption per unit of bodyweight" and growth rate expressed as a percentage of bodyweight it is concluded that most, though perhaps not quite all, of the growth-promoting activity of penicillin for poults comes from stimulation of their appetite in the first 6 days of life.—K. J. Carpenter.

1448

LINDGREN, N. O. **Studies in the growth promoting action of antibiotics in poultry nutrition.** 3. *Nord. Vet.-Med.*, 1954, **6**, 701-706. [State Vet. Med. Inst., Stockholm.] German and Swedish summaries.

A group of 60 White Leghorn cockerels was kept in a wire-floored cage from hatching to 4 weeks of age and fed on a ration of fishmeal 7.5, meatmeal 3.5, oilseed meals 13, wheat germ 0.5, alfalfa meal 3, a vitamin concentrate (rich in vitamins A and D and in riboflavin) 5, cod liver oil 1, minerals 1.5, wheat bran 24, yellow maize meal 15, and dredge maize to 100. Their mean finishing weight was 238 g.

A second group received the same diet with a dietary supplement of *Bacterium coli* as previously used (*Proc. 15th Internat. Vet. Congr.*, 1953, 913) and finished with a mean weight of 228 g. Further groups that received, respectively, 5 p.p.m. procaine penicillin, penicillin and *Bact. coli*, and 5 p.p.m. neomycin and *Bact. coli*, weighed 246, 255 and 254 g. The failure to obtain a growth stimulus with a dietary supplement of *Bact. coli* alone is in disagreement with the author's earlier findings.

Serial samples of droppings and of crop contents were taken from the birds in the different groups, and serial dilution, plating and counting methods were used to measure their content of coliform organisms. The day-to-day variations were extremely high and the counts bore no obvious relation to the diets.—K. J. Carpenter.

1449

LINDBLAD, G. S., SLINGER, S. J. and MOTZOK, I. **Effect of aureomycin on the calcium and phosphorus requirements of chicks and poults.** *Poultry Sci.*, 1954, **33**, 482-491. [Dept. Poultry Husb., Ontario Agric. Coll., Guelph.]

In the first experiment, groups of 15 day-old Columbian Rock female chicks were given a maize and soya bean ration deficient in Mn (18 p.p.m.) and supplemented with all combinations of 0.4, 1.0 and 1.8 per cent. Ca and 0.2, 0.4 and 0.6 per cent. inorganic P in the presence and absence of 25 p.p.m. aureomycin hydrochloride. The effects of the antibiotic, Ca and P levels and the interactions of Ca and P on the liveweight gain were significant at $P < 0.01$. Maximum liveweight was obtained with 1.0 per cent. Ca and 0.4 per cent. inorganic P in the presence of the antibiotic, but in its absence inorganic P had to be raised to 0.6 per cent. The presence of the antibiotic tended to reduce the incidence of perosis, except in the presence of high amounts of Ca. It is suggested that bone calcification alone is not a suitable criterion for the evaluation.

tion of mineral requirements when antibiotics are included in the ration. Aureomycin supplements produced a clear increase in bone ash with 0.4 per cent. Ca ration and a decrease when the ration contained 1.0 and 1.8 per cent. Ca.

Experiment 2 was similar to experiment 1 except that the basal ration contained 55 p.p.m. aureomycin and the supplements were 1.0 and 1.8 per cent. Ca and 0.40 and 0.6 per cent. inorganic P. On the basis of liveweight gain the effects of inorganic P and aureomycin were significant at $P < 0.01$; the effects of Ca and all interactions were non-significant. The effects of aureomycin on the Ca and P levels required for maximum growth were similar to those in experiment 1, but there was no consistent effect on bone ash.

In experiment 3, groups of 20 day-old Barred Plymouth Rock male chicks were used in an experiment similar to No. 1, with supplements of 1.0 and 1.4 per cent. Ca and 0.4 and 0.6 per cent. inorganic P. On a liveweight basis, only the effect of the aureomycin was significant. The maximum weight was obtained with rations containing 1.0 per cent. Ca and 0.6 per cent. inorganic P in the presence of the antibiotic and 1.0 per cent. Ca and 0.4 per cent. inorganic P without it, the effect being opposite to that observed in experiment 1 when females were used.

In experiment 4, groups of 9 males with 9 female day-old Broad Breasted Bronze turkey poult were given an adequate ration containing all combinations of 2.0 and 2.5 per cent. Ca and 0.4, 0.55 and 0.85 per cent. inorganic P in the presence and absence of 25 p.p.m. aureomycin hydrochloride. The effect of antibiotic supplements was significant on a liveweight basis for all poult, but was greater for males than for females. With or without antibiotic, optimum growth of males was obtained with a level of 0.55 per cent. inorganic P at either level of Ca; with females the levels were 0.4 per cent. inorganic P and 2.0 per cent. Ca. Raising the Ca level from 2.0 to 2.5 per cent. had an adverse influence on the feed to gain ratio.

In the last experiment groups of 8 male with 8 female poult were given an adequate ration with supplements of 1.0 per cent. Ca and 0.4 per cent. inorganic P and all combinations of 1.5 and 2.0 per cent. Ca and 0.3, 0.4 and 0.5 per cent. inorganic P with and without 25 p.p.m. aureomycin hydrochloride. The liveweight data indicated that the effects of aureomycin and sex and their interaction were significant at $P < 0.01$, and the effect of P was significant at $P < 0.05$. Males responded to the antibiotic to a greater extent than females. In the absence of antibiotic, maximum growth was obtained with 1.0 to 1.5 per cent. Ca and 0.4 per cent. inorganic P; with antibiotic the corresponding levels were 2.0 per cent. Ca and 0.5 per cent. inorganic P.—M. J. Head.

MORRISON, A. B., HUNSAKER, W. G. and AITKEN, J. R. Influence of environment on the response of chicks to growth stimulants. *Poultry Sci.*, 1954, 33, 491-494. [Poultry Div., Central Exp. Farm, Ottawa.]

Eight groups of 50 New Hampshire \times Barred Plymouth Rock day-old chicks were given to appetite a basal ration of 34.3 per cent. maize-meal, 34.3 per cent. ground wheat, 20 per cent. soya bean oilmeal, 4 per cent. meatmeal and 2.5 g. grassmeal with mineral and vitamin supplements. Supplements of 10 g. procaine penicillin, 90 g. 3-nitro-4-hydroxy-phenylarsonic acid, 90 g. arsenic acid or 2 lb. ethomid C/15 (a surface-active agent) per ton were given to duplicate groups of chicks. One group from each pair was housed in new starting batteries with raised wire floors in a building disinfected since it was previously used; the other group was brooded in floor pens in a large brooder house used for other chicks immediately before the experiment.

At 4 weeks of age in the old environment only penicillin produced significantly heavier birds. At 6 weeks of age, it produced significantly heavier birds in both environments, but the effect was greater in the old. The arsenic acid compound produced a growth response equal to that of penicillin in the old environment but was without effect in the new. Neither of the other growth stimulants produced a growth response in either environment. There was also evidence that the sexes responded to the different rations and environments in different ways.

Efficiency of feed utilisation was greater for chicks in the old environment, and penicillin or 3-nitro-4-hydroxy-phenylarsonic acid improved the efficiency in the old but not in the new environment.—M. J. Head.

POTTER, G. C. and KUMMEROW, F. A. Chemical similarity and biological activity of the saponins isolated from alfalfa and soybeans. *Science*, 1954, 120, 224-225. [Dept. Food Technol., Univ. Illinois, Urbana.]

Saponins extracted from alfalfa leaf meal were hydrolysed and 3 genins were separated on an alumina column. A sample of soyasapogenol B was prepared by the method of Ochiai *et al.* (*Ber.*, 1937, 70B, 2083) and from its infrared spectrum it appeared to be closely related to the first of the 3 alfalfa genins.

Purified saponins from both alfalfa and soya beans inhibited growth in chickens, but their genins did not. Part of the growth depression in chickens and the occurrence of bloat in cattle may be caused by soyasapogenols; with cooking these would be hydrolysed to non-toxic genins. The process of dehydration is too mild to hydrolyse the saponins of alfalfa.—D. Harvey.

SUNDE, M. L., CRAVENS, W. W., BIRD, H. R. and HALPIN, J. G. The effect of complete and

incomplete growing diets on subsequent performance of the laying hen. *Poultry Sci.*, 1954, 33, 779-784. [Dept. Poultry Husb., Univ. Wisconsin, Madison.]

Groups of 60 Single Comb White Leghorn chicks were given a basal maize and soya bean oilmeal ration with or without 0.05 per cent. penicillin supplement (Merck 626) and 3 per cent. condensed fish solubles; these rations were termed "complete" and "incomplete". Cockerels were removed at 6 to 8 weeks of age and the pullets culled to about 24 per group. All pullets received a similar laying ration from 20 weeks of age.

The complete ration gave more rapid growth than the incomplete ration. The difference between the growth rates was maximum at 8 weeks of age, but continued until the birds were housed for laying trials. The feed to gain ratio indicated that the complete ration gave the best results to 8 weeks of age and the incomplete ration thereafter. No difference in egg production, mortality or overall feed consumption was found between the groups. Sexual maturity of the birds reared on the incomplete ration was 10 to 12 days later than in the other birds and egg size was initially larger.—M. J. Head.

1459

OLOUEFA, M. M. Influence of thyroprotein and darkness on Egyptian chicken during summer. *Poultry Sci.*, 1954, 33, 649-652. [Coll. Agric., Univ. Cairo, Giza.]

Groups of forty-five 2- to 3-year-old Egyptian hens were housed in concrete rooms at night and in an open yard in the daytime. One group received a supplement of 5 g. thyroprotein per 100 lb. feed, a second group was housed in the dark for 2 hr. at midday at a temperature 18° to 23° F. below the surroundings, while the third group acted as control.

Over the 3-month experimental period thyroprotein significantly stimulated egg production (13 per cent.) but had no effect on egg weight; the hens lost bodyweight steadily. Group 2 produced significantly more eggs, 6.2 per cent., than the controls, but there was no effect on egg weight. The hens of this group lost bodyweight continuously during the experiment; the controls did not.—M. J. Head.

1460

FRENCH, M. H. and LEDGER, H. P. The deep-litter system. *East African Agric. J.*, 1954, 20, 40-44. [Joint Animal Indust. Div., East African Agric. Forestry Res. Organiz.]

Three groups of pullets were placed, a month before laying began, in deep-litter houses (1) and were given a dry mash of maize meal 44, pollards 30, alfalfa meal 10, meatmeal 10, cottonseed meal 10, salt 1, limestone 3, bonemeal 2 and dried

yeast 2 parts. They also received a daily grain feed of equal parts of oats, millet and barley, scattered on the litter. Three comparable groups were in deep-litter houses and had access to grass runs (2); and 3 further groups were in houses with bare-earth floors with access to grass runs (3). During the growing season green grass was hung in the intensive deep-litter houses, and during the dry season kale was hung in all pens.

Over a laying period of 12 months the mean egg yields in houses 1, 2 and 3 were 146, 146 and 162, respectively. There was no difference in feed consumption between the groups.

Variations in egg production through the year could not be related to the prevailing weather. The 3 groups used for each system of housing were one of Cambars, one of Legbars and one of Welsummers, and there was a suggestion that the breeds differed in their adaptability to deep litter.

CHARLET, P., CHARLET-LÉRY, G. and LEROY, A. M. Utilisation de levure de distillerie dans l'alimentation des volailles. [Use of distiller's yeast in poultry feeding.] *Ann. Zootech.*, 1952, 1, No. 4, 33-42. [Lab. Recherches Zootech., Inst. Nat. Agronom., Paris.]

A group of 10 laying birds received to appetite for 12 months a ration of dried distiller's yeast 12, oilseed meals 23, wheat germ 3, miller's offals 8, alfalfa meal 5, bonemeal 4, ground limestone 5.5, barley 20 and maize meal 20 parts; this ration contained 21.5 per cent. of crude protein. In addition, they received 30 g. oats for every 70 g. of the mixed ration consumed. Their mean egg production was 110. A second group similarly fed had 8 parts of distiller's yeast from the mixed ration replaced by only 6 parts of meatmeal to maintain the total crude protein content at the same level; their mean production in the same time was 108 eggs. The fertility and hatchability of the eggs were similar.

A group of chicks was reared on a ration of cereals, fine bran, alfalfa meal and oilseed meals, supplemented with 3 per cent. of lactalbumin and 9 per cent. of mixed blood-, meat- and fishmeal. They also received cod liver oil and an allowance of sprouted oats. At 60 days of age 13 cockerels had a mean weight of 800 g. and 16 pullets of 760 g. per head. In a parallel group receiving 14 parts of dried distiller's yeast in place of the 9 parts of mixed animal protein concentrates in the ration the mean weights at 60 days were 880 and 770 g. for cockerels and pullets, respectively. The group receiving yeast appeared to grow feathers more rapidly and more evenly.

In a further trial chicks were reared to 60 days on a good commercial starting ration supplemented with 10 per cent. of either dried brewer's or dried

distiller's yeast. The performance of the chicks was equally good with either supplement.

BALLOUN, S. L. Effect of high level aureomycin feeding on rate of egg production. *Poultry Sci.*, 1954, 33, 867-869. [Dept. Poultry Husb., Iowa State Coll., Ames.]

New Hampshire pullets were housed in wire-floored cages in groups of 9 to 12. One group which was fed on an all-vegetable ration supplemented with vitamin B₁₂ gave 35 per cent. production in the second 8-week period of the trial, and 36 per cent. in the third period. Two similar groups gave a mean of 37 per cent. production in the second period, and in the third period, when their ration was supplemented with 110 mg. aureomycin per kg., a mean of 46 per cent. Further groups received 3 other rations which included 2 per cent. of fish solubles; their egg production after receiving aureomycin was also generally higher than that of unsupplemented birds, but the differences were less than in the groups receiving the all-vegetable ration.

HØIE, J. and SANDVIK, Ø. Forsøk med kokte poteter, potetsurfer og potetgrøpp til verpehøner. [Experiments with cooked potatoes, potato silage and potato meal for laying hens.] *Meld. Norges Landbrukshøgsk.*, 1954, 34, 81-129. [Norges Landbrukshøgskole.] English summary.

Experiments were made with duplicate groups each of 40 or 42 pullets in the 3 years 1949-51 with steamed potatoes, silage of steamed potatoes and silage from raw potatoes, and in 1951 with single groups of 25 pullets with silage of raw potatoes steamed before use and pulped raw potatoes dried in a herringmeal drier. The controls had daily 40 to 50 g. whole grain, 50 g. sour skimmed milk and a mixture of cereal meal, extracted oilseed meal, herringmeal, grassmeal, yeast, cod liver oil and minerals, to appetite. The experimental groups received about 33 g. potato dry matter daily with about 20 g. whole grain, 50 g. sour skimmed milk and a still richer concentrate mixture to appetite.

Egg production was slightly higher in the controls than in any of the potato groups and less in the group with silage of raw potatoes than in the others. When the data for feed consumption were computed to the same liveweight and egg production, the value of potatoes for hens was estimated to be, in terms of Scandinavian feed units per 100 kg. potato dry matter: steamed 90, silage from steamed potatoes 92, silage from raw potatoes 57, steamed silage from raw potatoes 76 and dried potatoes 89.—I. Leitch.

OTHER BIRDS

1464

GROMOV, I. M. and EGAROV, O. V. Materyaly po pitaniyu i khozyaistvennomu znacheniyu filina yostochnogo Pamira i Kopet-Daga. [Data on diet and economic significance of the eagle owl of the Eastern Pamir and Kopet-Dag.] *Zool. Zh.*, 1953, **32**, 964-978. [*Zool. Inst., Acad. Sci. SSSR.*]

This study of the diet of the eagle owl (*Bubo bubo*) in these regions was made in connection with the protection of birds that prey on harmful rodents and in order to establish the proportion of

harmful and useful animals in the diet of these birds. Investigation of a considerable number of droppings in both regions showed that it was impossible to generalise about the proportion of harmful to useful animals, as this varied from one district to another. In the Eastern Pamir the percentage of useful animals in the diet of the eagle owl was 70.48 per cent. and of harmful ones 9 per cent.; in Kopet-Dag the percentage of useful animals was 3.72 per cent. and that for harmful ones 91.31 per cent.—H. Scherbatoff.

FOOD ECONOMICS AND STATISTICS

WYLLIE, J. Land requirements for the production of human food. A study of the experience of the United Kingdom during the years 1936/9 to 1949/50. *Wye Coll., Dept. Agric. Econ.*, 1954, pp. 38. Price 4s.

Reasonable calorie values are assumed per unit weight of crop and livestock products used for human foods, and are applied to the official statistics of U.K. Agricultural Output for the 3-years 1936-39 and for each year from 1939-40 to 1949-50 inclusive. In relating this calculated total yearly calorie output as human food to the utilisation of land, deductions are made from the total acreage of crops and grass (rough grazings are estimated to contribute only 1 per cent. of calorie output) for the areas of "industrial" (e.g., flax) and non-edible crops (e.g., flowers and nursery stock). Deductions are also made for hay (300,000 acres), barley and oats not for human food (200,000 acres) and certain other crops, much of which must have been used for feeding the livestock whose output of human food calories is included in the output calculations. No allowance is made for "imported acreage", as the imports of feeding-stuffs which again contribute to human food calorie output from livestock may be termed. [Thus the calculations of the acreage required to supply the one million Cal. estimated to be the mean annual requirements per head of population are likely to be low.] The figures given are 1.78 acres of crops and grass in 1939-40, only 1.15 acres in 1943-44, 1.54 acres in 1947-48 and 1.28 acres in 1948-49-50.

Crops contributed 47 per cent. of annual calorie production in 1939-40, 71 per cent. in 1943-44 and 59 per cent. in 1949-50, and it is concluded that maximum calorie production depends largely on a large acreage of high-yielding crops of wheat, potatoes and sugar beet. Thus the rather lower calorie production per acre in 1949-50 is associated with a smaller wheat acreage and an increase in the number and milk yield of dairy cows. Under these circumstances the cost per million Cal. is higher, but the "quality" of the output is improved (i.e., greater output of protein, vitamins, etc.). This should be considered in deciding the optimum combination of crops and livestock for national food production.

Calorie production per man has increased over the years (apart from the poor harvest year of 1947-48), a peak of 149 being achieved in 1943-44 (1936-39 = base 100). In 1948-49-50 the production per man averaged 137. This increase is believed to be mainly due to more efficient farming methods including greater use of mechanisation and fertilisers.—J. L. Corbett.

1467

BARKER, A. S. Fertility and grassland productivity. *J. Brit. Grassland Soc.*, 1954, **9**, 47-51. [Imperial Chemical Industries, Ltd., Central Agric. Control.]

Productivity of grassland is measured by the amount effectively utilised in commercial farming and is more useful in practice than measures of herbage yield, which reflect fertility, the degree to which a soil can sustain the growth of plants. Figures are presented to show the relation between the intensity of the use of grass in feeding dairy cows and the cost of feeding, average milk yield and profit margin per cow. At higher levels of grass feeding, yield and profit margins are reduced,

but the investment return on the total cost of production remains a constant percentage. More information is needed to decide what levels of grassland fertility and productivity are optimum on a farm and national scale.—J. L. Corbett.

1470

BREIMYER, H. F. **Sources of our increasing food supply.** *J. Farm Econ.*, 1954, 36, 228-242. [U.S. Dept. Agric.]

The population of the United States has increased from 96 million in 1910-14 to 152½ million in 1950 and agricultural production has more than kept pace with this increase. Although the average amount of food consumed per person has decreased by 2 per cent, the quality of the diet has improved considerably, particularly as regards minerals and vitamins. The Bureau of Agricultural Economics index, which combines quantity of food consumed with price weights, shows that total consumption expanded by 77 per cent. during the above period. This increase in production is allocated to the following major factors: increase in area of cropland harvested 10 per cent., acres of cropland freed from non-food crops 2.5 per cent., feed obtained from pasture 4.4 per cent., reduction in number of horses and mules 14.8 per cent., yield of crop per harvested acre 43.5 per cent., rate of output per ton of feed 15.2 per cent., shift in consumption from butter to margarine 2.5 per cent.

Forecasts of population in 1975 range from 199 to 221 million and the possibilities for further increase in agricultural production to meet new demands are discussed. By a process of elimination it is suggested that further increase in agricultural production can come only from increased productivity of the land now under cultivation.

1471

ASHEBY, A. W. **The seasonality of milk sales in England and Wales from 1936-7 to 1951-2.** *J. Agric. Sci.*, 1954, 44, 274-287. [Dept. Agric. Econ., Univ. Nottingham.]

Vol. 26, No. 1

Sales were examined for each of the 11 marketing districts and for the country as a whole. During the 16 years under study, total milk sales off farms increased from 990 million gal. in 1936-37 to 1530 million gal. in 1951-52. An examination of milk prices, daily sales and number of calves born daily showed that there was little correlation between the extent of seasonal variations in milk values and milk sales; farmers got their cows to calve when prices were rising or at their highest, even though higher milk prices in winter did not make winter milk production more profitable.

W. Thomson.

1472

SMITH, H. L. **Report on costs of milk production for the year ended 30th September 1953.** *Edinburgh and East of Scotland Coll. Agric., Dept. Econ., Bull.* No. 43, March 1954, pp. 38.

Forty-nine herds in the south-east of Scotland were surveyed. Average herd size was 51 cows, milk production 778 gal., 47 per cent. being produced during the winter half-year, when costs were 11d. (50 per cent.) more per gal. Feed accounted for 61 per cent. of gross costs, labour for 19 per cent. and herd maintenance for 5 per cent. High-yielding herds gave the greatest profit. Mean herd replacement during the year was 25 per cent. Costs per cow have risen over the 3-year period from 1950-51 largely because of a 3 per cent. increase in feed costs, and these were only partly offset by increased yields and not at all by higher milk prices. Compared with 1936-37 the average yearly milk yield of cows in surveyed herds has increased by only 11 gal. Profit per gal. increased 10 times since, while cost per gal. increased by 172 per cent. and income per gal. increased by 251 per cent. Greater use was made of home-produced concentrate foods, grazing and silage, and less of purchased foods and of roots.

J. L. Corbett.

GODFREY, D. **Breeding cattle costs 1952-1953.** *North of Scotland Coll. Agric., Agric. Econ. Dept. Econ. Rep.* No. 40, April 1954, pp. 15.

Forty-two farms, grouped according to location (at average altitudes from 180 to 650 feet above sea level and from 3½ to 16½ miles from the north-east coast of Scotland) and the system of wintering cattle, were surveyed. Outwintered herds were mainly Galloway or Highland breed. Winter-housed herds were Shorthorn and Aberdeen-Angus. Feed cost for the winter period was 48 to 55 per cent. of the total cost per cow per year.

Housed cattle ate 94 to 118 cwt. turnips and swedes, 12 to 18 cwt. oat straw, 1 to 4 cwt. oats plus miscellaneous feedingstuffs per head from November to early May. Outwintered herds ate 15 to 41 cwt. turnips and swedes, 1 to 15 cwt. straw, up to 3 tons silage or 10 cwt. hay per head, plus small quantities of miscellaneous feedingstuffs.

KELLY, J. H. and OWEN, W. F. Beef production in north eastern New South Wales. *Agric. Gaz. N.S.W.*, 1954, 65, 282-288; 289.

The area contains about 600,000 beef cattle or about one-quarter of the beef cattle population of New South Wales. The cattle industry is based on natural pasture. There is little attempt to improve pasture and supplementary feeding of stock is not practised. If the problems of winter starvation and deficiencies in pasture could be overcome it is estimated that beef production could be improved by 20 to 30 per cent.

J. S. Thomson.

1476

JOUBERT, D. M. Breeding for beef in tropical and sub-tropical climates, with special reference to the continent of Africa. *Colonial Plant Animal Prod.*, 1954, 4, 1-13. [Sch. Agric., Cambridge.]

Although potential agricultural production in tropical Africa is enormous, present production per unit of land or per animal is much lower than in temperate countries. Prospects for increasing animal products are discussed and the difficulties are emphasised, chief among which are problems of animal adaptation to climate, scarcity of pasture in certain areas and the variation in the nutritive value of pasture. The best policy would appear to lie in improvement of indigenous stock by selection, and the advantages of the Afrikaner, with its slower growth and maturing characters, are pointed out.—J. S. Thomson.

NEUVIK, O. and PATERSON, D. G. Marketing lambs. Comparison of liveweight method and carcass weight and grade method. *S. Dakota Agric. Exp. Stat. Bull.* No. 416, December 1951, pp. 12.

Results of this preliminary study showed that lambs of greater than average carcass weight tended to be underestimated by liveweight graders

and those below average to be overestimated. Errors were greater in estimating carcass weight than in estimating grade, but because of price differentials between grades, grade and weight errors had about the same influence on financial returns. Differences of up to \$3 per cwt. in returns to producers occurred when actual carcass grades and weights were used instead of the buyer's estimate of grade and weight.—J. C. Gill.

MATZEN, E. H. Trends in the competitive position of poultry products relative to red meats. *Poultry Sci.*, 1954, 33, 682-686. [Res. Div., Poultry Branch, P.M.A., U.S. Dept. Agric.]

Compared with the years 1935-39, consumption of turkeys per head in U.S. in 1950-52 increased by 96 per cent. and of chickens by 58 per cent. compared with an increase in beef and veal consumption of only 6 per cent. Prices paid to poultry producers increased by 71 to 99 per cent. as compared with an increase of 291 per cent. for beef and 244 per cent. for lamb producers. The retail price for chickens increased only by 76 per cent., that for beef by 181 per cent. It is concluded that efficiency of production has increased more for poultry than for livestock.—J. S. Thomson.

SWART, F. W. J. Verwerkingsmogelijkheden voor dierlijke vetten. [Possibilities of using animal fats.] *Tijdschr. Diergeneesk.*, 1954, 79, 601-607. [Hoogland.] English, French and German summaries.

The effective demand for animal fat is less than the supply and because of its natural lack of antioxidants transport is difficult and wastage high. It could be used more extensively in industry, e.g.,

N.A. and R., January 1955

to make plastics pliable and in the manufacture of anticorrosives and synthetic rubber, and it could be used in stock feeding. Cattle can take up to 4 per cent. of the dry matter of rations and poultry 8 per cent. The surplus fat in the United States would be used up if 1 per cent. were added to the rations of beef cattle. Rancidity should be prevented by addition of anti-oxidants and mixing in rations and absorption made easier by addition of surface-active agents.—I. Leitch.

DIET IN ETIOLOGY OF DISEASE

GENERAL

1486

EVANS, W. C., EVANS, E. T. R. and HUGHES, L. E. Studies on bracken poisoning in cattle. 1. *Brit. Vet. J.*, 1954, 110, 295-306. [Dept. Agric. Chem., Univ. Coll. N. Wales, Bangor.] An account is given of experiments made during 1949 and 1950.

In the first experiment a daily feed of 11 lb. hay and 5 or 6 lb. bracken (433 lb. bracken eaten over 80 days) had no toxic effect on heifers. In a second experiment cattle fed to appetite on recently harvested green bracken alone died of bracken poisoning similar to that found naturally. Two oz. dried yeast added daily to the same feed had no effect on the disease, nor had the parenteral administration, after the onset of signs, of glucose and vitamin B₁ or a vitamin B complex containing vitamin B₁, riboflavin, nicotinamide, pantothenic acid, pyridoxine, inositol, biotin, *p*-aminobenzoic acid, folic acid and choline chloride. A fall in leucocytes occurred before the appearance of clinical signs and the erythrocyte level fell in the terminal stages of the disease.

For the third experiment 6-month-old calves were fed as in the previous experiment. The parenteral administration of vitamin B₁ with or without the vitamin B complex during the whole experiment did not affect the onset of the disease. Pronounced leucopenia was seen in calves dying from bracken poisoning. Addition of 1 to 2 lb. molasses to the bracken either dry or after steaming prevented the disease.—A. Hepburn.

1487

CORDY, D. R. Nigropallidal encephalomalacia in horses associated with ingestion of yellow star thistle. *J. Neuropathol. Exp. Neurol.*, 1954, 13, 330-342. [Univ. California Sch. Vet. Med., Davis.]

A study was made of 16 cases of a nervous disease of horses, occurring in Northern California and becoming more commonly recognised, known locally as "chewing disease". All occurred on dry weedy pastures in which yellow star thistle

(*Centaurea solstitialis*, L.) provided most of the available forage, and ceased when horses were moved to better pastures or given hay. No case has been reported in a ruminant.

The onset is sudden, with a variable impairment of eating or drinking, a fixed or "wooden" facial expression due to hypertonia of the muscles of the muzzle and face, but no flaccid paralysis. The animals remain standing drowsily, and chewing. Movements are made even when there is no food in the mouth. There is no excitement, loss of appetite or pyrexia. The course varies from a few days to a few weeks.

At post mortem no transmissible agent was demonstrated, the outstanding lesions being focal necrosis in the anterior portions of the pallidum and substantia nigra. Their distribution was usually bilaterally symmetrical. Three horses fed on yellow star thistle developed typical signs, and in 2 of them the distinctive nervous lesions were found at post mortem. The pathogenesis of the disease is discussed at length, and it is suggested that the lesions may result from damage to the neurons consequent upon anaemic hypoxia.

JENSEN, R., CONNELL, W. E. and DEEM, A. W. Rumenitis and its relation to rate of change of ration and the proportion of concentrate in the ration of cattle. *Amer. J. Vet. Res.*, 1954, 15, 425-428. [Sch. Vet. Med., Colorado Agric. and Mech. Coll., Fort Collins.]

In the first experiment 95 fattening cattle from 12 to 18 months of age were divided into 5 groups. All received a basal fattening ration providing, per head daily, maize 8 lb., barley 4 lb., linseed meal 1 lb., alfalfa 4 lb. and maize silage 10 lb. Two groups received also 1 lb. CaCO₃ per head daily. At the beginning of the experiment all the cattle were fed on alfalfa only, and the change to the fattening ration was made gradually over 12 or 30 days. Four cattle from each of 4 groups were killed after 35 days and the rest after 133 days.

In all the groups there were animals with rumen inflammation, but the extent was significantly

greater in the groups which changed to the fattening ration in 12 days. CaCO_3 did not protect. The rumen inflammation was acute in animals killed after 35 days and chronic in those killed later.

In the second experiment 37 Hereford steers aged 14 months were divided into 5 groups and received different proportions of alfalfa and the fattening ration. They were killed at about the same weights, after 192 to 213 days. The group which received 1 part alfalfa to 3 parts concentrates had significantly more rumen inflammation than those in which the ratio was between 1:2 and 2:1.—D. Duncan.

WORDEN, A. N., BUNYAN, J. and PICKUP, J. A **fatal hypocalcaemia-like syndrome in dairy cows following the excess consumption of fodder-beet.** *Vet. Rec.*, 1954, 66, 133-134. [Cromwell House, Huntingdon.]

At a dairy farm in southern England it was the practice to balance lush spring grass by giving mangolds at pasture. When the mangolds were suddenly replaced by fodder beet, the whole herd of 50 Guernsey cows was found with typical signs of hypocalcaemia within 24 hr. Despite treatment with calcium borogluconate, 6 animals died, and on post-mortem examination the rumen in each case was found to be heavily impacted, with actual separation of the mucosa and associated haemorrhage. Blood samples from other affected animals confirmed the existence of hypocalcaemia.

REDA, H. and OLOUFA, M. M. **Incidence of diseases and mortality among the Egyptian cattle and buffaloes.** *Brit. Vet. J.*, 1954, 110, 157-160. [Dept. Animal Breeding, Fac. Agric., Giza, Egypt.]

From a survey made in Egypt during the years 1943 to 1952, and covering 261 buffaloes and 394 cattle, it was concluded that the incidence of disease was significantly higher in cattle than in buffaloes, although the mortality rate was about the same in both species. The chief causes of disease were enteritis, metritis, mastitis, pneumonia and impaction, tympanites and indigestion. The authors suggest that the preference for buffaloes in Egypt may be due not only to the higher butter-fat content of their milk but also to the greater freedom from disease.—W. A. Greig.

BEVERIDGE, W. I. B. and JOHNSTONE, I. L. **Sheath-rot, non-contagious posthitis or chronic ulceration of the prepuce of sheep. 3. Curative effect of reduced food consumption or surgical measures.** *Austral. Vet. J.*, 1954, 30, 1-6. [Div. Animal Health Prod., C.S.I.R.O., McMaster Animal Health Lab., Sydney.]

Because sheep affected with sheath-rot usually recovered when brought from the field to the laboratory, it was thought that recovery might be due to the enforced starvation during transit or to voluntary semi-starvation on arrival when they were offered an unaccustomed diet. Other possible explanations were the altered diet and the changes of environment.

A series of laboratory and field experiments demonstrated that fasting had a definite curative effect on both internal and external posthitis lesions. There was some evidence that the factor responsible was the change from an alkaline to an acid urine which followed fasting; drenching with sodium bicarbonate maintained the urine alkaline, and there was a high mortality among animals treated in this way. On the other hand, ammonium chloride, while it induced an acid urine, was less effective than fasting. Further trials indicated that reduced water intake was not responsible, and the mechanism was not completely elucidated.

A few cases did not respond to fasting, and in these a surgical method was devised for alleviating the condition. See Abst. 3991, Vol. 24.

HARTLEY, W. J. **"Stiff lamb disease" in New Zealand.** *N.Z. Vet. J.*, 1953, 1, 137-142. [Wallaceville Animal Res. Stat., Dept. Agric., Wellington.]

A specific myopathy affecting lambs aged from 6 days to 6 weeks, which die after approximately one week, has occurred in New Zealand either spontaneously, following the driving of ewes and lambs off lush clover pastures or, over a period, in lambs whose mothers were grazing a predominantly red-clover sward. The signs and lesions closely resembled the "stiff lamb disease" as it occurs in Britain and the U.S. The chief lesions at post mortem were gelatinous oedema of the subcutaneous tissues and the appearance of gross focal or diffuse pale areas in the muscles, particularly those of the hind legs. Cardiac lesions, chiefly a focal gray discolouration of the endocardium of the right ventricle, or chalky sub-endocardial plaques, were frequently seen. The single specimen of urine examined for creatinine and creatine contained excessive quantities. Histologically, the muscle lesions were necrosis, often with calcification. Widespread vacuolation of the hepatic

parenchyma and dilatation of Bowman's capsule and lesions in the glomeruli and the convoluted and collecting tubules of the kidney were common.

It is considered highly probable that the pathological process is similar to that of "stiff lamb disease", but that under New Zealand conditions, with a plentiful supply of green feed, an uncomplicated vitamin E deficiency seems unlikely.

THOMAS, G. and EDEN, A. A peculiar nutritional dermatitis in pigs. *Nature*, 1954, 174, 553. [Nat. Agric. Advisory Serv., E. Province, Anstey Hall, Trumpington, Cambridge.]

Pigs of 10 to 12 weeks of age frequently developed characteristic dermatitis with acute irritation. Appetite and gain of weight were impaired and recovery was slow. This condition was found only when the pigs were dry-fed, even when water was freely available, and was not controlled by oil or powder dressings, dipping, bathing or spraying with insecticide. The inclusion of fodder beet or potatoes in the feed produced an improvement, and wet-feeding rapidly cured the condition.

A. Hepburn.

1497

LUDVIGSEN, J. Undersøgelser over den såkaldte "muskeldeneration" hos svin. 1. [Studies of so-called "muscle degeneration" in pigs. 1.] *Forsøgslab. København Beretn.*, 1954, No. 272, pp. 105. English summary.

"Muscle degeneration" is defined as a condition in pigs in which the skeletal muscles lose colour so as to resemble chicken or fish flesh, and have a high water content and a sour smell; the muscle is easily teased into its component bundles and fibres. When all or nearly all groups of muscle are affected, the disorder is described as "total muscle degeneration"; clinical signs are dullness, high temperature, dyspnoea, cyanosis, trembling and weakness, but most affected pigs show no sign in life.

At slaughter the pH of muscle is low, about 5.3 instead of 6.4; the liver is enlarged and there are haemorrhages in both liver and kidney. External muscles are more affected than internal. The

heart muscle is usually light in colour and of abnormal texture. Microscopically the muscles are oedematous with fluid between the fibres, and often ruptured. There may be infiltration of leucocytes and connective tissue cells where fibres have ruptured. Otherwise no great change is found except in the thyroid, where the alveoli are filled with colloid, the cells are flat and the nuclei small and stain heavily. Death is preceded by severe haemorrhages in all parenchymatous and endocrine tissues.

The incidence, as measured at slaughterhouses, is higher in summer than in winter and deaths are most frequent in July and August. The disorder is not more common in one area than in another. In the year 29 September 1952 to 1 October 1953, out of 12,724 pigs delivered at co-operative slaughterhouses, 3.4 per cent. had "total muscle degeneration".

Experiments based on the post-mortem findings in the thyroid showed that muscle changes resembling those in this disorder could be produced by giving pigs methylthiouracil and prevented by giving iodinated casein. Further experiments with a pig herd which had been badly affected showed that iodinated casein prevented the disorder where controls from the same litters were all severely affected.

Biochemical findings in blood and muscle are described. Serum K rises and Na falls. The cause of death is thought to be shock. [It is not anywhere suggested that the pigs suffering from this disorder were given methylthiouracil.]—I. Leitch.

1498

INNES, J. R. M. and YEVICH, P. P. So-called nutritional muscular dystrophy as a cause of "paralysis" in rabbits. *Amer. J. Pathol.*, 1954, 30, 555-565. [Med. Labs., Chem. Corps, Army Chem. Centre, Md.]

In routine pathological examinations of more than 100 rabbits special attention was given to the skeletal muscles. In 24 animals there were lesions of the paravertebral muscles and in 16 of these there were macroscopic lesions, haemorrhagic streaks intermingled with pallid spots and areas of necrosis, sometimes accompanied by wasting and impaired locomotor activity. In the other 8 there were only microscopic histological lesions and the rabbits appeared plump and healthy. All the rabbits had been kept for weeks or months on a stock rabbit pellet supposed to contain all the constituents essential for rabbits.

It is suggested that such spontaneous lesions may occur frequently. They are indistinguishable from the lesions described in so-called experimental nutritional muscular dystrophy and may be a source of error in clinical interpretation of results.

D. Duncan.

1499

ARGUTINSKAYA, S. V. K voprosu ob obrazovanii mochevykh kamnei u norok. [The formation of stones (in the bladder) in mink.] *Karakul. Zverovodstvo*, 1953, 6, No. 4, 47-53. [All-Union Sci. Res. Lab. Fur Animals.]

A study of animals suffering from the disease throughout the several sovkhoses led to the conclusion that deaths were caused by phosphatic and not by urate stones. The overall mortality was low, 1 per cent. of the total mink population, but on some sovkhoses it was as high as 64 per cent. of the entire herd and 50 per cent. of the pups. The highest mortality was among the females towards the end of pregnancy and among the very young pups.

The stones consisted of Ca and Mg phosphate, carbonates of Ca and Mg, a small amount of sulphates, silicic acid and ammonium magnesium phosphate. Their composition showed that they were formed in the alkaline medium of the urine, and it is recommended that the acidity of the ration should be increased. Their formation is ascribed to a breakdown in metabolism during growth, pregnancy and lactation and it is considered that feeding can have only a predisposing effect. Possible conditions favouring stone formation could be an increased alkalinity of the ration and an excess of mineral matter in the food.

H. Soherbatoff.

COFFIN, D. L. and HOLZWORTH, J. "Yellow fat" in two laboratory cats: acid-fast pigmentation associated with a fish-base ration. *Cornell Vet.*, 1954, 44, 63-71. [Angell Mem. Hosp., Boston, Mass.]

Post-mortem examinations were made of two 7-month-old littermate cats, one male and one female, which had been maintained from the age of 6 weeks on a commercial canned cat food said to consist of a fish base with supplements of cereals, grassmeal, groundnut and linseed meals, molasses and salt. When 5 months old, the male had shown symptoms of anorexia, oedema of the legs and body, and weight loss, but had recovered after injections of liver extract and feeding on horse-meat and milk. The female had also lost weight at about the same time, showing in addition stiffness in the joints, but had recovered spontaneously. Both made poor weight gains, however, and shortly before death they developed nervous disturbances, chiefly opisthotonos and muscular spasms. Coma followed.

The findings in both were similar, the features being rough dry fur, pale mucous membranes and loss of subcutaneous fat. This fat, and also that in the mesenteric, omental and retroperitoneal regions, showed striking changes, being soft in consistency and deep yellow or light rusty-brown in

colour, with bright red or red-brown streaks and flecks. Histologically, the fat was seen to contain a yellowish pigment of a strongly acid-fast character, often in islands scattered among normal adipose areas, which resisted ordinary fat solvents. Globules of fatty material had been broken down into small masses which had become phagocytosed, and in some places amorphous precipitated material was also present.

Because of the similarity of these changes to those observed in several other species fed on diets containing large amounts of unsaturated acids but low in vitamin E, it is suggested that the adipose discolouration had a similar etiology.—W. A. Greig.

DEFICIENCY DISEASES

1501

BAUER, H. Mangelschäden bei landwirtschaftlichen Nutztieren in Baden. Ursachen und Bekämpfung vom Standpunkt des Tierarztes, Züchters und Landwirts. [Deficiency diseases in farm animals in Baden. Causes and combating, from the point of view of the veterinary officer, the breeder and the farmer.] *Schriftenreihe über Mangelkrankheiten*, 1953, No. 3, pp. 152. English summary.

This publication is both a broad review of the whole subject of deficiency diseases and the outcome of practical and scientific work during many years of investigations in the State of Baden. It has been produced at the request of a subcommittee of the German Society for Agriculture which was set up to consider means of combating deficiency diseases.

After an outline of the economic losses due to deficiency diseases in Baden, the occurrence of different types of such diseases in different areas in the State as reported by veterinary practitioners is tabulated and shown on a map. The different types of soils, their underlying geological formation and their possible influence on the occurrence of deficiency diseases due to the low quality of the flora and grazing herbage are discussed. The use of fertilisers and their influence on animal health through their effect on the quality of the crop are also considered. Information in the literature on the selective feeding habits of different classes of stock is reviewed, and 48 medicinal plants with their main constituents are listed.

Individual deficiency diseases and their possible causes and treatment are then discussed. Amongst these are rickets and osteomalacia, tetany in cows, licking disease (pica), "tongue-playing" in cattle, Darre, Hinsch- and Semperkrankheit, which appear to be similar or allied diseases possibly due to cobalt deficiency, growth disturbances in young animals due to inadequate feeding (mineral and vitamin deficiencies), goitre, *haematuria vesicalis bovis*, and acetonæmia in cows.

N.A. and R., January 1955

The whole problem of feeding errors and the losses arising therefrom and proposals for their remedy are considered in a further chapter and directions are given for the supplementary feeding of minerals, including trace elements and vitamins, where necessary, to farm animals.—W. Godden.

1502

RIEHM, H. *Étude et traitement du mal du "Hinsch" dans une ferme du nord de la Forêt-Noire. Essai sur le rôle du cobalt à l'état de traces. [Treatment of "Hinsch" disease on a farm to the north of the Black Forest. Role of traces of cobalt.] Ann. agronom., 1954, 5, 349-359. [Inst. Nat. Exp. Recherche Agronom., Augustenberg, Baden-Württemberg.]*

The disorder was studied in cattle on a mountain farm near Baden-Baden, where rearing of young stock was impossible because of this disease. The signs were loss of appetite, pica, loss of weight and poor milk production, progressive weakness and often death of young animals. The cattle were housed for a long winter season and fed only on home-produced hay.

The farm lay on the north face of a granite hill; 2 neighbouring farms on different soils were not affected. The total Co content of soil samples from the affected farm ranged from 0.4 to 0.6 p.p.m., in samples from the other farms from 0.4 to 6.22 p.p.m. Lactate-soluble Co in samples from the 3 farms showed mean values of 0.053, 0.143 and 0.140 p.p.m., respectively, and on the affected farm 21 out of 24 samples contained less than 0.06 p.p.m. Samples of hay from the 3 farms were analysed in 3 successive years, and the mean Co content was 0.039 p.p.m. on the affected farm and 0.101 and 0.100 on the others. Values for Mo, Cu, Zn, Fe and Mn were all within the normal range.

Five cows slowly improved when given 0.5 kg. molasses, making up their total Co intake to 0.9 mg. daily, but a young heifer failed to improve. Spectacular improvement occurred when this heifer received 2.0 mg. Co as sulphate daily, and in 2 other animals given 1.0 mg. daily in the drinking water.

It is concluded that the disease is an uncomplicated cobalt deficiency.—D. Duncan.

OSBORNE, A. D., FEATHERSTONE, J. and HERDAN, G. *Cobalt deficiency in Herefordshire and Worcestershire. 1. Field observations.*

TRIBE, D. E. and OSBORNE, A. D. *2. Laboratory investigations. Vet. Rec., 1954, 66, 409-413; 413-414. [Univ. Bristol Vet. Sch., Langford, Somerset.]*

1. On 9 farms in north-west Worcestershire and

Vol. 25, No. 1

north Herefordshire, where soil analyses showed a low Co content, groups of lambs were given cobalt sulphate equivalent to 14 mg. Co every fortnight during the summer and autumn. Both treated and control lambs were treated against worms. On 6 of the farms Co gave an advantage in improving the growth of the lambs; the difference in male lambs was significant in 3 successive years, in females only in the last year, 1953. In 1949, a dry summer, no result was significant.

2. Four pining lambs from one of the farms included in the above experiment were studied in the laboratory. One lamb received 100 µg. vitamin B₁₂ by intramuscular injection 3 times weekly and showed an immediate increase in appetite and in bodyweight. Two responded rapidly when given Co by mouth at the rate of 7 mg. weekly. The fourth lamb was untreated and maintained its bodyweight throughout the experiment but failed to grow. The deficiency was considered to be "borderline".—D. Duncan.

1504

BROOKSBANK, N. H. *Anaemia in piglets associated with a copper deficiency. Vet. Rec., 1954, 66, 322-324. [Vet. Invest. Centre, Sutton Bonington.]*

Two litters of pigs aged 4 to 5 weeks affected with severe anaemia responded poorly to intramuscular Fe. The 8 piglets of a second-litter sow were then treated with intramuscular Fe on the fourth and tenth days of age. Growth rate continued satisfactorily for a fortnight, but the Hb concentration dropped steadily, and did not improve even when FeSO₄ was given by mouth. The anaemia was hypochromic, with a number of nucleated red cells but very few reticulocytes in the peripheral blood. CuSO₄ by mouth, with or without FeSO₄, was introduced at 26 days, and continued for 5 days; 3 days later clinical and haematological improvement was apparent, and the blood picture soon became normal.

The anaemia was associated with an abnormally high lymphocyte : neutrophil ratio. This remained unaffected by Fe, but was corrected by Cu.

CUNNINGHAM, U. J. *Molybdenum and animal health in New Zealand. N.Z. Vet. J., 1954, 2, 29-36. [Wallaceville Animal Res. Stat., Dept. Agric., Wellington.]*

Trials are in progress all over New Zealand to discover in which areas molybdenum may be beneficial to pasture and arable land. The role of Mo in peat scours of cattle is discussed: the condition is considered to be Mo intoxication associated with pasture levels of Cu not in themselves low enough to account for Cu deficiency, but where the Cu is rendered unavailable by the antagonistic

effect of Mo. Experiments are reported which demonstrate that on most New Zealand types of soil a small dressing of Mo materially increases the Mo content of the pasture. Mo should therefore be used with great caution on soils known to produce pastures low in Cu, and always in the smallest effective amounts.—D. Duncan.

MATHEU, M. Observations sur les effets de la carence phosphorique en Beauce. [Observations on the effects of phosphorus deficiency in Beauce.] *C.R. Acad. Sci.*, 1954, 239, 648-650.

Cattle on the chalky soil of Beauce, which contained about 0.11 per thousand of assimilable P_2O_5 and 8 per thousand of exchangeable CaO, showed osteomalacia, pica and poor production. Two groups of 4 cows in milk received similar rations of local feeds, but the crops supplying one group were grown on land topdressed with superphosphate. The intakes of dry matter, N and Ca were similar, but the crops from topdressed land contained about twice as much P as the others. The cows receiving more P were cured without other treatment and their milk yields were 44 per cent. greater than those of the cows with low P intake; 2 of the latter had osteomalacia and the others were in poor condition.—D. Duncan.

1508

TODD, J. R. The phosphorus status of cattle in part of Central Province, Kenya. *East African Agric. J.*, 1954, 20, 66-68.

Values as low as 0.13 per cent. P_2O_5 in the grass dry matter have been recorded during the dry season in Kenya. Contents of 0.5 per cent. or over are rare. Pica in cattle, mainly earth eating, is widespread. Estimations of the inorganic P content of the blood of 202 native-owned cattle showed that while none fell below 2 mg. P per 100 ml., 25 per cent. had less than 4 mg. per cent. and were considered subnormal. Animals in good condition had the lowest content, P supply probably being adequate for maintenance in poor condition but not for the demands of production also. It is suggested that for increased animal production in this area P supplements must be provided.—J. L. Corbett.

SUOMELA, H., KÄMÄRÄINEN, P. and PALOHEIMO, L. Kokeita ns. Promeca-rehulia. [Experiments with Promeca food mixture.] *Maataloust. Aikakausk.*, 1954, 26, 112-115. [Dept. Animal Husb., Univ. Helsinki.] English summary.

Promeca is a patented food mixture containing 4 per cent. calcium chloride, 46 per cent. beet molasses and 50 per cent. wheat bran and is recommended as protection against low blood Ca. In feeding experiments with chickens and ewes no harmful effect was noted even when large amounts of Promeca were given.—J. S. Thomson.

1511

ALLCROFT, R., SCARNELL, J. and HIGNETT, S. L. A preliminary report on hypothyroidism in cattle and its possible relationship with reproductive disorders. *Vet. Rec.*, 1954, 66, 367-371. [Vet. Lab., Minist. Agric., Weybridge, Surrey.]

Thyroid glands from 5 aborted foetuses were examined histologically and chemically; 3 were heavier than normal. In some there was evidence that stimulation had occurred and in others that their I contents were either below or near the critical level of 0.03 per cent. of fresh weight suggested by Marine and Lenhart (*Arch. Int. Med.*, 1909, 4, 440) as that below which hyperplasia might occur.

Estimations of blood iodine were made in a number of herds in which abortion was a problem and in a number of suitable control herds. A breed difference was found for the amount of protein-bound I in plasma; ranges and mean values in μg . per 100 ml. were for 23 Guernsey cows 3.2 to 4.0, 3.42, for 20 Ayrshires 2.8 to 3.6, 3.12, and for 20 Friesians 2.4 to 3.2, 2.90. In affected herds of 2 of these breeds corresponding data were for 23 Guernseys 1.6 to 3.2, 2.22 and for 7 Friesians 0.8 to 1.6, 1.09; these means were lower by amounts statistically significant.

During the investigation some remarkably high values for total I in blood plasma were encountered, but they were found to exist in cows which had been given seaweed meal in their production ration, or, in one case, where the animal had had an intra-uterine injection of I solution. Less spectacular increases were seen in heifers which had been receiving a mixture of concentrates containing KI. In each of these groups the increases were almost entirely in the inorganic fraction; protein-bound I in the plasma was raised only slightly.

The water supply used by each herd was analysed for I and hardness. The difference between the mean values per litre, 3.25 μg . I for control herds and 2.87 μg . for affected herds, was not

N.A. and R., January 1955

statistically significant. Findings for milk yields, reproductive efficiency and incidence of abortion and calving abnormalities are tabulated.

Work is being continued to test further the association of reproductive disorders with low levels of blood I in cows and with the thyroid characteristics in foetal calves.—D. Harvey.

1512

STAUB, H. Die Behebung der Aufzuchtverluste bei Ferkeln mit Hilfe von Infrarot-Strahlern. [Reduction of losses of young pigs with the help of infrared rays.] *Berl. Münch. tierärztl. Wochenschr.*, 1954, 67, 281-285. [Vet. Hyg. Inst., Justus Liebig Hochsch., Giessen.] English summary.

By the use of infrared rays breeding losses among young pigs were reduced to a minimum. Even in cold, wet housing conditions, where the yearly losses had previously amounted to 35.5 per cent. (46.7 per cent. in winter), the losses after infrared ray treatment were reduced to 1.3 per cent. In moderate housing conditions (cold, but relatively dry) the losses were reduced from 17.5 to 1.3 per cent., and in good housing conditions from 11.5 to 1.1 per cent. After 3 weeks the infrared rays could be partly shut off, and after 4 weeks removed altogether; the young animals then continued to thrive.—M. B. Richards.

DISEASES OF METABOLISM

1513

INGLIS, J. S. S., WEIPERS, M. and MARR, A. Some observations on bovine hypomagnesaemia. *Vet. Rec.*, 1954, 66, 353-354; 355. [Vet. Sch., Univ. Glasgow.]

Six deaths occurred among 22 suckling cows continuously grazing during mild weather in winter. No feeding supplement had been available. Blood samples from 8 of the remaining cows showed values ranging from 0.58 to 1.27 mg. per cent. Mg. The protein content of the herbage was low, but Mg and Ca were normal. Two lb. hay and the equivalent of 2 oz. MgO given daily prevented further death, and serum Mg rose by about 80 per cent. after 5 weeks.

Four cattle grazing without supplementary feeding from the end of July showed no difference in serum Mg from 4 cattle kept inside and fed on hay and small amounts of concentrates until mid-October. The Mg level in the grazing cattle then fell significantly to 1.05 mg. per cent. after 3 weeks. Giving hay rapidly raised the Mg to a safety level. Weather was concluded to have no direct effect on serum Mg.—A. Hepburn.

MAPLESDEN, D. C. Propylene glycol in the treatment of ketosis. *Canad. J. Comp. Med.*, 1954, 18, 287-293. [Dept. Med., Ontario Vet. Coll., Guelph.]

Routine cases of bovine ketosis, 8 primary and 2 with slight metritis, were given twice daily by mouth 250 g. (7 cows) or 125 g. (3 cows) propylene glycol for 4 days.

Response to treatment was significant in all cases. One cow relapsed 8 days after the end of treatment but recovered completely after re-treatment. The higher level of propylene glycol produced more rapid recoveries than the lower level, which was considered too slow for routine farm practice.—A. Hepburn.

1516

JOHNSON, R. B. The treatment of ketosis with glycerol and propylene glycol. *Cornell Vet.*, 1954, 44, 6-21. [Live Stock Sanit. Serv. Lab., Univ. Maryland, College Park.]

Since it is now known that the ruminant absorbs little glucose as such, but depends for its energy supplies on the products of rumen fermentation, the problem of the treatment of ketosis may be regarded as one of finding an inexpensive glucogenic material which is not destroyed by rumen micro-organisms and which does not leave undesirable residues upon oxidation.

A number of substances were considered, including propionic acid, tripropionin, glycerol, propylene glycol and sodium propionate. Of these, propylene glycol was regarded as the most satisfactory. Glycerol also was effective but expensive. Nine dairy cows with ketosis were treated with glycol, 7 with propylene glycol and 2 with both, response being judged by appetite, milk yield and plasma glucose and ketone body levels, which were measured at intervals. An initial dose of 2.25 kg. glycerol, followed by up to 1 kg. daily, was expensive but gave generally excellent results; so also did daily doses of 200 to 800 g. propylene glycol, which was much cheaper. Propionic acid is considered unsatisfactory because in large doses it causes acidosis and irritation, tripropionin is immiscible in water, unpalatable and expensive, and adequate doses of sodium propionate raise the animals' CO₂ capacity, with resulting loss of appetite, owing to the excessive liberation of sodium ions.

W. A. Greig.

1517

MILLER, W. J., TYZNICK, W. J., ALLEN, N. N. and SORENSSEN, D. K. The treatment of ketosis in dairy cows by oral administration of sodium acetate. *J. Amer. Vet. Med. Assoc.*, 1954, 124, 291-294. [Dept. Dairy Husb., Univ. Wisconsin, Madison.]

Because of the fact that sodium acetate in the rumen is rapidly absorbed and can be converted into carbohydrate, its value as an aid to the treatment of ketosis was tested on 49 cows showing clinical signs. In 34 of these blood sugar and blood urine ketones were measured before treatment and at intervals thereafter.

Sodium acetate was given in amounts varying from $\frac{1}{2}$ lb. to 1 lb. daily. Of the 34 cows, 18 recovered with no other treatment, 16 of them within 2 weeks. Six developed complications, and 10 failed to respond. Of the 10, only one responded to any other treatment. The 15 other cows with clinical signs of ketosis also were treated with sodium acetate, and made satisfactory clinical recoveries.

It is admitted that controls without treatment were not used, as they were not available, but if the acetate treatment was not beneficial then the frequency of spontaneous recovery from ketosis may be so high as to obviate the justification for any routine treatment whatever.

Other points in favour of sodium acetate as a treatment for ketosis are that it is inexpensive, is readily obtainable, is not unpalatable, appears to have a stimulating effect on appetite, is non-toxic, is compatible with other treatments, and by increasing the alkali reserve of the blood, may contribute to the relief of any accompanying acidosis.—W. A. Greig.

1518

McLINTOCK, J. and WILKINSON, G. T. Acetonaemia in a litter of Samoyed puppies. *Vet. Rec.*, 1954, 66, 416-417. [Norwich.]

Severe ataxia accompanied by nodding movements of the head and muscular tremors was seen in six 4-week-old puppies. All had diminished pedal reflexes, bloated abdomen and breath smelling of acetone. The acetonaemia diagnosed was traced to a high fat intake and consequent fatty infiltration of the liver. A diet of glucose, water and NaHCO_3 , and the injection of glucose, saline and vitamin B_{12} cured 4 puppies.

POISONS OCCURRING IN FOOD

1521

OGILVIE, D. D. "Chronic" copper poisoning of sheep. *Vet. Rec.*, 1954, 66, 279-282. [I.C. (Pharmaceuticals), Ltd., Wilmslow, Manchester.]

An outbreak occurred among sheep grazing under controlled conditions on 85 acres of orchard which had at intervals been sprayed with cuprous oxide equivalent to 10 lb. Cu per acre. The flock was not allowed access until at least 14 days after spraying, but 27 deaths occurred at intervals between 2 weeks and rather more than 2½ months after spraying ceased. Post-mortem examinations were made of 3 sheep, of which one had died between 24 and 36 hr. earlier and for it the findings were of little value because of decomposition. The second had marked signs of disease and was examined 3 hr. after death and the third, which had no sign of disease, was killed and underwent immediate examination.

The second sheep appeared not to have lost appetite, was deeply jaundiced and showed almost complete degeneration of the liver. The third was in excellent condition. Fe, As, Cu, Co, Pb and Zn were estimated in liver, kidney, rumen contents and small intestine of both animals; these data are tabulated. The Cu content of the liver of sheep 3 was in fact higher than for sheep 2, but in the kidneys the reverse was true, sheep 2 having between 3 and 4 times the amount in sheep 3.

The Cu content of the pasture was estimated in 4 paddocks; 2 months after spraying it ranged between 80 and 250 p.p.m. and after 5 months between 10.3 and 15.0 p.p.m. Control pastures averaged 8 p.p.m. It was calculated that 2 months after spraying the intake must have been about 1 g. Cu daily.

The description "chronic" refers only to the time taken for signs to appear and, depending on the copper status before ingestion of the increased amounts, this may range between 20 and 100 days. Once signs develop the disorder is acute and death results in 1 to 4 days.—D. Harvey.

1522

SCHMIDT, H. J., NEWELL, G. W. and RAND, W. E. The controlled feeding of fluorine, as sodium fluoride, to dairy cattle. *Amer. J. Vet. Res.*, 1954, 15, 232-239. [Stanford Res. Inst., Calif.]

In an area in Arizona where cattle are naturally exposed to a high level of F in their drinking water, it was found that the safe borderline level of ingestion of soluble F by cattle is about 1 mg. F

N.A. and R., January 1955

per kg. bodyweight daily. This estimate is in accord with conclusions derived from a study of the literature.

To extend knowledge of the effects of long-term ingestion of soluble F, an experiment is being conducted with cattle over a period of 5 to 6 years; this paper is an interim report. Four groups of 4 cattle are being given sodium fluoride in their grain rations at rates providing total F intakes of from 1.0 to 2.5 mg. per kg. bodyweight daily. A fifth group, receiving no NaF supplement, has an intake from natural sources of from 0.15 to 0.3 mg. F per kg. bodyweight daily, and serves as a control.

So far it has been found that only slight mottling or staining of the fourth pairs of incisors, with no wear, has occurred in the 1 mg. group. At the 1.5 mg. level, mottling and staining were more evident, but at the 2 higher levels severe, and there was also wear. Lesions were less frequent and less intense in the third pairs of incisors, and only one cow has developed any change in the first and second pairs of incisors.

Slight exostosis has developed in 3 of the 4 cows at the 2.5 mg. level, but in none of the others. None of the animals has lost weight or developed diarrhoea, rough coat, "lapping of water", or elongation of the toes, and milk production has not diminished. General health has been satisfactory, although at the peak of milk production there has been a transitory unthriftness in cows of the 2.5 mg. group.

Urinary excretion of F has reflected the level of intake.—W. A. Greig.

1523

NEELEY, K. L. and HARBAUGH, F. G. Effects of fluoride ingestion on a herd of dairy cattle in the Lubbock, Texas area. *J. Amer. Vet. Med. Assoc.*, 1954, 124, 344-350. [Dept. Animal Husb., Texas Technol. Coll., Lubbock.]

Forty cows in an area where the water supply had a fluorine content of 4 to 5 p.p.m. were examined for signs of fluorosis. It was calculated that the average daily ingestion of F was 0.52 mg. per kg. bodyweight over 3 years, and 1.69 mg. per kg. bodyweight during the succeeding 3 years, the increased amount resulting from the introduction of a commercial feed.

Mottling, staining and abnormal wear were evident in the incisor teeth of all of the cows, most severe in teeth which were being formed at the time of the rise in F intake. In cows ingesting large quantities of F over 6 years, the dental lesions were very marked and were similar to those generally accepted as being caused by fluorosis. However, there was no skeletal lesion, stiffness, diarrhoea or elongation of the hoofs, and no abnormality in milk and butterfat production or in

breeding efficiency, which could be attributed to the high fluorine intake.—W. A. Greig.

1524

PETRO, A. W. Studies on fluorosis of sheep. 2. The toxicity of waterborne fluoride for mature grazing sheep. *Austral. J. Agric. Res.*, 1954, 5, 545-554. [Div. Biochem., C.S.I.R.O., Univ. Adelaide, S. Australia.]

During a 26-month trial, 3 groups of mature Merino wethers on pasture were given drinking water with F concentrations of 0.3, 10 and 20 p.p.m., respectively. Groups receiving water containing 10 and 20 p.p.m. F drank only 0.5 litre per head daily in winter, with negligible F intake, and 3 to 4 litres per head daily in summer, 0.4 and 0.8 mg. F per kg. bodyweight for the 2 groups, respectively. No significant difference was found between the 3 groups with regard to health, bodyweight or weight of wool. In no group was any mottling or uneven wear of the teeth seen. F concentrations in bones and teeth were 0.04 to 0.06 per cent. on the dry fat-free tissue in the control group, and 0.08 to 0.13 per cent. and 0.09 to 0.18 per cent., respectively, in the groups given water with 10 and 20 p.p.m. F. Results of indoor trials with younger sheep are compared and discussed.—J. G. Gill.

1526

HARVEY, J. M. Flock management to control fluorosis of Merino sheep in Queensland. *Queensland J. Agric. Sci.*, 1953, 10, 127-159. [Biochem. Sect., Chem. Lab., Div. Plant Indust.]

Four groups of 20 Merino lambs aged 3 months were treated for 30 months as follows: (1) continuously on water containing 10 p.p.m. F, (2) 3 months on water with 10 p.p.m. F and 3 months on F-free water alternately, (3) 6 months on and 3 months off the F-containing water, and (4) 6 months on and 6 months off the water. The sheep were fed on poor quality alfalfa hay. Monthly inspection of the incisor teeth showed that damage by fluorine was greatest in groups 1 and 3. Mild fluorosis occurred in group 2 and only in this group was there no uneven wear of the molars or premolars. Six sheep from each group were slaughtered at the end of the experiment, and photographs of the incisor teeth and X-ray plates of the femur, tibia and mandible of these were shown. No abnormality was detected in the bones. Analyses of these bones, teeth and the

kidney showed F concentration to be lowest in group 2. There was no difference between groups in liveweight gain or wool growth. A rotation is recommended to allow young sheep protection from fluorinated water for at least 3 months and exposure for no longer than 3 months. Sheep over 30 months and breeding sheep may be kept on fluorinated water (concentration up to 10 p.p.m. F) but lambs must be given F-free water. See Absts. 1408, 2674, Vol. 24.—J. C. Gill.

1527

HALLGREN, W., KARLSSON, N. and WRAMBY, G. Molybdenförgiftning ("molybdenos") hos nötkreatur i Sverige. [Molybdenum poisoning, "molybdenosis", in cattle in Sweden.] *Nord. Vet.-Med.*, 1954, 6, 469-480. [Vet. Forsöks-avd., Skara.] English and German summaries.

The occurrence is described of molybdenum poisoning on a farm in the direction of the prevailing wind and on a pasture only 100 metres distant from the chimney of an iron-smelting factory which uses molybdenum in the smelt. Cattle grazing this pasture became severely ill with acute diarrhoea; convulsions also occurred.

The blood serum of 2 cows contained 0.7 and 1.0 mg. Mo per litre about a week after removal from the contaminated pasture; 2 samples of grass contained 231 and 204 mg. per kg. dry matter, and the blood serum of 2 horses, still grazing on the pasture but perfectly healthy, 1.1 and 1.4 mg. Mo per litre. Normal values from a farm where the pasture contained only 0.4 p.p.m. of dry matter, the average of samples over 2 years, were for a cow about 0.03 and for a horse 0.02 mg. per litre. The normal value of Swedish pasture, from the results of a wide survey (Karlsson, unpublished) is 1.5 mg. per kg. dry matter. Samples from the contaminated pasture in the following summer, when it was not grazed, gave 159, 81 and 74 p.p.m.

It was computed that the chimney emitted about 50 kg. ash daily, containing MoO_3 and MoS_3 .

In an experiment, a heifer and a dry cow from a farm 7 km. from the chimney were given a single intravenous injection of 0.5 g. $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ ($\equiv 0.13$ g. Cu) and were then put to graze on the contaminated pasture. Serum Mo values were: initially 0.02 and 0.02 mg. per litre; after 8 days 2.1 and 2.1, and after a month 2.0 and 1.9. A month later still, when brought in, both were still healthy. The Cu content of this pasture was normal or above normal, 9.3 p.p.m. in 1952.

Post-mortem examination of one heifer that died after treatment with Ca, Mg, sugar and B vitamins showed congestion in the intestine and mesenteric lymph glands, subendocardial haemorrhages in the left heart and fatty liver.—I. Leitch.

1528

DOUGHERTY, R. W. and CELLO, R. M. Studies of the toxic factors in rumen ingesta of cows and sheep. 2. *Proceedings Book*, 1952, 130-137. [Dept. Physiol., New York State Vet. Coll., Ithaca.]

For part 1, see Abst. 5783, Vol. 19.

The introduction of 3 or 4 lb. of cracked cereal grains into the rumen of sheep caused atony of the rumen, intense depression, sometimes tenderness of the feet, and death in 5 out of 6 animals. The rumen liquor and the plasma of peripheral and portal blood of such sheep was toxic to normal sheep and dogs, causing a fall of blood pressure and leucopenia. Dogs lost their sensitivity after repeated injections. Antihistamines provided some degree of protection, but the material was not destroyed by a histamine preparation known to destroy histamine. Attempts to identify the toxic material were not successful.—A. T. Phillipson.

1529

PENNY, R. H. C. Suspected poisoning by fodder-beet in the bovine. *Vet. Rec.*, 1954, 66, 134. [Leighton Buzzard.]

A young Guernsey cow gained access to a fodder beet clamp and consumed an unknown amount of this material. She was found unable to rise, with evidence of digestive disturbance, but no tympany. Faeces were passed in only small amounts. Next day the animal was on her feet, but very dull. Her temperature was 103°F ., she refused all food, and ground her teeth; ruminal movements were in abeyance. Her condition worsened progressively, and her temperature rose to 104.6°F ., with pulse rate 90 per min. Rumenotomy was performed and quantities of ruminal contents were removed. Despite this she died on the fourth day. Post-mortem examination revealed diffuse patchy inflammation of the lining of the rumen, reticulum, abomasum and intestines. Liver and kidneys were pale and blotchy, and the heart showed haemorrhages along the course of the coronary vessels. Blood samples taken during the illness revealed that serum Ca and inorganic P both were slightly low.

It is concluded that death resulted from toxæmia following the absorption of some irritant principle. It is suggested that the absence of fibre in the rumen when the roots were consumed contributed to the ruminal atony.—W. A. Greig.

TRETHEWIE, E. R., GAFFNEY, F. M. and GLADWELL, P. J. Pharmacological studies of grasses

N.A. and R., January 1955

obtained from a property where "tall fescue lameness" in cattle occurs. *Austral. J. Exp. Biol. Med. Sci.*, 1954, **32**, 207-211. [Dept. Physiol., Univ. Melbourne.]

Cattle grazing on tall fescue (*Festuca arundinacea*) developed characteristic vasoconstriction and dry gangrene. Extracts of this grass and of the harmless ryegrass (*Lolium perenne*) were made in 0.6 per cent. acid saline. The neutralised extracts were injected into the femoral vein of cats whose vagi had been cut and the carotid blood pressure was recorded.

Both extracts acted as vasopressors, the fescue extract after a delay; the ryegrass extract, which was more powerful, produced an immediate increase smaller than the later main rise in blood pressure. The response to adrenaline after injections of the extracts was slightly greater. The pressor effects were evidently mediated through the adrenals, as was shown by the negative response after adrenalectomy.

The isolated cat uterus was stimulated and the isolated rat uterus inhibited by both extracts. The response of the rat uterus diminished with repeated doses of extract, but the inhibitory effect of ergometrine was unaltered. In the cat uterus grass extracts did not inhibit the response to adrenaline. It was concluded that the effect of the grass extracts was not caused by a substance of ergotamine type.—A. Hepburn.

1534

RAMAKRISHNAN, S. P., BHATNAGAR, V. N., PRAKASH, S. and MISRA, B. G. Effect of milk diet on *Plasmodium gallinaceum* infection in its vertebrate and invertebrate hosts. *Indian J. Malariol.*, 1953, **7**, 261-265. [Malaria Inst. India, Delhi.]

With fowls, milk diet provided no protection, but rather the reverse, against multiplication in the blood of *P. gallinaceum*.—E. M. Hume.

1535

RICHARD, R. M., SHUMARD, R. F., POPE, A. L., PHILLIPS, P. H., HERRICK, C. A. and BOHSTEDT, G. The effect of certain mineral supplements on lambs infected with the stomach worm (*Haemonchus contortus*). *J. Animal Sci.*, 1954, **13**, 694-705. [Dept. Animal Husb., Univ. Wisconsin, Madison.]

In the first experiment additional cobalt in the diet of lambs infested with *Haemonchus contortus* appeared to benefit the parasite and not the host. There was a great increase in worm egg production in the cobalt-fed lambs, although there was no difference in the number of adult worms between the dietary groups at autopsy. Anaemia was present in the heavily infested lambs and most severe in the Co group.

A second experiment was set up to find out if Ca and P affected the results. Additional Ca and P were given in the form of steamed bonemeal. Apart from a more rapid initial increase in egg count, the lambs given Co or Co plus steamed bonemeal did better, in all measurements taken, than the lambs getting the basal diet or basal diet plus steamed bonemeal alone. Observations were made on weight gains, egg counts, Hb, vitamin B₁₂ and nicotinic acid content of the blood and rumen ingesta, plasma Ca and the market price and quality of the animals.—G. C. Hunter.

1536

HIRCH, A. and LAWRENCE, W. E. Experimental infection with *Mycobacterium johnei*. 1. The effect of a low calcium diet on the disease in goats. *J. Comp. Pathol.*, 1954, **64**, 102-115. [Dept. Vet. Pathol., Univ. Liverpool.]

Eight 2-month-old kids were infected by drenching with gut scrapings from cattle with Johne's disease, or by a combination of drenching and an intravenous injection of a fluid culture of *Mycobacterium johnei*. The drenching and injection were repeated after 10 days. Four were given a normal diet, with cod liver oil supplements, and 4 were given a low-Ca but otherwise similar diet; one of these was also given KH₂PO₄ to limit its absorption of Ca.

Two of the control kids developed signs of Johne's disease, and were killed after 39 and 36½ weeks. The remaining 6 were killed from 28 to 41 weeks after the first infecting dose. At post-mortem examination, which included cultural examinations and counts of clumps and acid-fast organisms in intestinal smears, there was no obvious difference between the groups, except that the control animals had calcified lesions in the mesenteric lymph nodes but those on the low-Ca diet had not.—W. A. Greig.

7. BOOK REVIEWS

1537

HORDER (Lord), DODDS, C. and MORAN, T. **Bread. The chemistry and nutrition of flour and bread, with an introduction to their history and technology.** Constable and Company, Ltd., London, 1954, pp. vii + 186.

The authors of this book, representing as they did administrative, academic and commercial interests in bread, were well qualified to bring together, digest and summarise under one cover the vast information available on the subject. The book does not profess to be a complete review of literature for the specialist research worker, although every chapter has its bibliography. Nor is it for the general public. It is intended mainly for that section of the public which has a scientific background, doctor, science teacher, social worker, dietitian and the like.

The book begins with a short history of bread, which apparently was made in 2600 B.C. in much the same way as now. There follow an account of the types of wheat now used and their sources and a description of milling and baking techniques. The use of chemical improvers such as agene is discussed. The chapters devoted to the chemistry, digestion and assimilation of wheat, flour and bread summarise concisely the large modern literature. The contribution of flour and bread to the diet is assessed and the relative nutritive value of breads made from flours of different extraction rates and enriched flour are discussed. These chapters present a very clear picture of the importance of flour and bread in the U.K. diet. They supply about one-quarter of energy requirements and more protein than any single food, as well as being a rich source of B vitamins and minerals. But bread is not usually the sole food, and this should be borne in mind when such questions as the relative merits of high extraction and enrichment of flour are discussed.

The authors are nothing if not fair, and a final chapter on bread and health considers the evidence that high bread consumption may have harmful effects such as contributing to obesity, causing rickets, dental caries and digestive tract disorders. Little positive evidence against bread is found except for the relatively recent discovery that patients with coeliac disease require the exclusion of wheat gluten from the diet.

The usefulness of this little book is enhanced by the addition of a subject index.—F. C. Aitken.

1538

KALE, G. T., BHUTANI, R. C., IYENGAR, N. V. R., BALU, V. and SANKARAN, A. N. (Eds.).

Technical aid to food industries. Proceedings of the Symposium held at the C.F.T.R.I. Mysore on 5th and 6th February 1953. Central Food Technol. Res. Inst., Mysore, 1954, pp. xvi + 270.

The Third Symposium was held at the Central Food Technological Research Institute, Mysore in February 1953. Its subject was Technical Aid to Food Industries and it was attended by representatives of government departments, universities and research institutes, the food industries and their associations and of FAO; its president was the Deputy Minister of Natural Resources and Scientific Research, New Delhi. This small book is a report of the 44 technical papers presented.

Their subject matter ranges widely from the large-scale baking and cereal-processing industries to the small-scale manufacture of *pan supari*, the betel-nut product, provision of which, in the Hindu household, is at once a mark of hospitality and a source of nutrient calcium. The Director of the Institute at Mysore estimated the annual turnover of the food industry in India to be 1500 crores of rupees, about £1125 million, and these papers indicate how seriously and scientifically the Indian manufacturers are considering those problems of the feeding of the population of India which are their particular concern.—D. Harvey.

1539

SWEETMAN, M. D. and MACKELLAR, I. **Food selection and preparation.** J. Wiley and Sons, Inc., New York, 1954, 4th ed., pp. ix + 645.

This is the fourth edition of a textbook first published by the senior author in 1932 under the title *Food Preparation*. The subject-matter is planned to accompany laboratory work on food selection and preparation and meal planning by students of home economics in America. Five yardsticks of relative values of foods are analysed in the first 5 chapters: nutritive quality, digestibility, sanitary quality, palatability or appetite appeal, and economy. The next 3 chapters on processing, preparation and general structure of foods complete that part of the book which is in general terms. The remainder, approximately two-thirds of the book, deals with the application of these yardsticks to particular foods in their natural state and after processing or preparation. There follows an appendix of food values in common portions of foods and a subject index.

The book is written in such detail that it can scarcely fail to meet the needs of the teachers and

N.A. and R., January 1955

students in the United States for whom it is intended. But since all the detail of necessity relates to American conditions the book can have but little appeal or usefulness elsewhere.

F. C. Aitken.

1540

COLONIAL OFFICE. **Malnutrition in African mothers, infants and young children. Report of Second Inter-African (C.C.T.A.) Conference on Nutrition, Gambia, 1952.** H.M.S.O., London, 1954, pp. 398. Price 25s. net.

This conference was held at the Medical Research Council's Field Research Station at Fajara, Gambia, under the auspices of the Commission for Technical Cooperation in Africa South of the Sahara (C.C.T.A.) and was attended by some 50 delegates and observers. Its report contains 36 communications and about as many summaries of demonstrations, discussions and other material.

Inevitably, perhaps, the conference was concerned chiefly with "kwashiorkor". The inverted commas are necessary, since it rapidly becomes clear that the delegates found it almost impossible to decide whether they were discussing one disease or several related diseases, or the manifestations of a single or multiple etiology. The chief value of the report may lie in the fact that it brings together many different sets of facts, opinions and approaches, which would otherwise have to be sought from a variety of sources. The fact that informal discussion is summarised brings the divergences most vividly to life.

In general, it seems that we must be satisfied for the time being with the knowledge that, in parts of Africa and elsewhere, where infants and toddlers are given highly unsuitable low-protein foods when the supply of breast milk fails, many of them become seriously ill. Their condition is characterised, more or less, by failure of growth, oedema, wasting of muscle (but not of subcutaneous fat), disturbances of food utilisation, liability to degenerative changes in the liver, moderate anaemia and various other signs possibly related to vitamin deficiencies, directly or indirectly produced. The common feature seems to be a low-protein diet. There is no sound evidence that infection with malaria or other communicable disease plays any essential part in the etiology. No one doubts that sound feeding practices would eliminate "kwashiorkor", but the puzzle is to get nourishing foods into the people and the children, even if the problem of supply were solved.

In the absence of any reasonably precise definition, there are few epidemiological facts about kwashiorkor, and the report has little to say about incidence. It apparently does not occur among Melanesians, "one of the few groups in the world still unaffected by what might be called 'western civilization'". While clinicians struggle with the

formidable problems of diagnosis and treatment, pathologists, biochemists and dietitians are concerned to narrow down the mechanisms and its etiology. Most of the contributions of the latter demonstrate that we have as yet no real integrating hypothesis which will weld together the scattered facts and speculations at our disposal and enable a specific programme of management to be devised. Dr. E. G. Holmes very properly underlined our lack of basic knowledge:

"It is necessary . . . to stress our lack of fundamental information about the nutrition, growth and general health of the African and to express the hope that a start will be made with the necessarily laborious and expensive process of obtaining information on these matters. Without such knowledge, progress will be hampered in many ways, not the least in that of devising effective preventative measures."

It is abundantly clear that kwashiorkor starts when the original symbiosis of the mother and her child breaks down and is not effectively replaced by the conditions necessary for wholesome independent life. Thus, kwashiorkor is rooted in the mother-child relationship. This aspect of the problem is dealt with so sketchily as to reinforce the impression of powerful ignorance of the fundamental facts. A paper with "mother-infant relationship" in its title is more speculative than factual, and another headed "Obstetrical data" is disposed of in 11 lines. The remaining papers under the general title "Maternal Malnutrition" deal with the behaviour of milk in the stomachs of rats; anaemia as an indicator of protein deficiency in pregnancy; anaemias of pregnancy in the Gold Coast; and serum calcium and magnesium levels in Dakar Africans.

In general, the report gives a good impression of the deliberations of a group of very puzzled experts, who without doubt must have gained individually from the interchange of ideas which the conference made possible. But, unless they lead to an acceleration of fundamental research, and of medical, economic and nutritional betterment, their formal conclusions will not help the malnourished African mother and her child very much.—A. M. Thomson.

1541

TURNER, D. **Handbook of diet therapy.** Univ. Chicago Press, Chicago, Ill., 1952, revised ed., pp. x + 138.

The second edition of this useful handbook, published in 1952, remains a practical manual to be used by qualified dietitians for the calculation and construction of "therapeutic" diets. Among useful new additions to this edition is a section on low-sodium diets and new tables dealing with the amino-acid content of foods.—S. J. Cowell.

1542

FISHER, R. B. **Protein metabolism.** Methuen and Co., Ltd., London, 1954, pp. ix + 198.

This book deals with the digestion and absorption of protein but with no mention of the peculiarities of ruminant digestion; the overall picture of protein metabolism; deamination, transamination and urea synthesis; general aspects of the metabolism of amino-acids; the use of isotopes in the study of protein metabolism; metabolic and endocrine interactions in protein metabolism, and the final chapter is on the nutritive value of proteins.

In the writing of this little book the author has attempted what he considers is more truly a "re-view" than a sequence of discoveries. He finds, for example, that "there is little evidence for the necessity for peptic digestion and little certainty of the occurrence of 'eruptic' digestion of proteins, but tryptic digestion seems essential to normal protein absorption". The evidence that the products of the digestion are amino-acids and that protein passes into the bloodstream in this form he considers is incomplete, and is at variance with the time taken for complete digestion of protein. Evidence for the chemical form of the products of protein absorption is believed to be unreliable.

The problem of the form of the normal products of absorption is held to be important, because it determines the course of investigation into the details of protein metabolism. It is suggested that there is enough evidence to consider seriously the possibility that peptides and not amino-acids are the normal currency of protein metabolism. The general interpretation adopted is that implicit in the notion of "continuing metabolism" known by early workers but first enunciated by Borsook and Keighley in 1935, namely, that synthetic processes, mainly those leading to cytoplasmic protein synthesis, are the immediate fate of the products of absorption of protein in the body. The author's special contribution is the emphasis on the incompatibility of this interpretation with the notion that the major processes of protein metabolism can be profitably studied by investigating the fate in the organism of individual amino-acids. The metabolism of protein is the metabolism of the amino-acids in concert. He holds that there must be a series of intermediate molecules of great importance, which must fall into the category of neglected peptides.

This is a provocative book.—D. P. Cuthbertson.

1543

Colloque sur les acides aminés, tenu à la Clinique Médicale Universitaire (Hôpital Nestlé) de Lausanne du 16 au 17 Avril 1953. [Colloquium on amino-acids, held at the Clinique Médicale

Universitaire (Hôpital Nestlé) in Lausanne, April 16-19, 1953.] *Exp. Med. Surg.*, 1954 12, 1-333.

The colloquium lasted 4 days, and there were 48 participants. The papers are in English, German and French, chiefly the last. Groups of papers were given on methods, chiefly chromatography and microbiological estimation; absorption and intermediary metabolism; amino-acids in the structure and synthesis of proteins, particularly in regard to haemopoiesis and plasma proteins; amino-acids in the blood and urine; and clinical problems and their treatment. The last section includes papers on the use of amino-acids in the treatment of hepatitis, tuberculosis, duodenal ulcer, anaemias, and kwashiorkor, and in the rearing of infants, particularly the premature. None of the papers is long. Many of them are followed by a discussion. Most of them have little or no bibliography, but a small number have quite a considerable one.—E. M. Hume.

1544

Colloque sur les acides aminés. [Colloquium on amino-acids.] S. Karger, Basle, 1954, pp. 333.

1545

DYKE, S. C., CRUICKSHANK, R., ALLOTT, E. N., MACFARLANE, R. G. and ROBB-SMITH, A. H. T. (Eds.) **Recent advances in clinical pathology.** J. and A. Churchill, Ltd., London, W. 1, 1951, 2nd ed., pp. xii + 575. Price 40s.

The second edition of this wellknown book is almost completely new. The General Editor states in the preface that only one-quarter of the subjects dealt with in the first edition have found a place in the second and that chapters dealing with these have been very largely rewritten. The 4 section editors covering bacteriology, biochemistry, haematology and histology have enlisted the support of 27 other contributors. No attempt can be made here to survey the material contained in the 31 separate chapters of the book. The volume represents a competent survey of the recent advances and will be invaluable to all clinical pathologists. Full working details are given of laboratory methods, with ample references to the literature.—H. A. Krebs.

1546

GREENBERG, D. M. (Ed.) **Chemical pathways of metabolism.** Volume 1. Academic Press, Inc., New York, 1954, pp. x + 460. Price 88s.

This is the first of 2 volumes. There are extensive well-connected accounts of glycolysis (Stumpf), the tricarboxylic acid cycle (Krebs), other pathways of carbohydrate metabolism (S. S. Cohen) and fat metabolism (Chaikoff and G. W. Brown), 2 chapters on more general topics, on free energy (Pardee) and on metabolic sequences

N.A. and R., January 1955

(D. E. Green) which overlap in some measure on the more specific chapters, and finally chapters on polysaccharide synthesis (Hassid) and on the metabolism of sterols and steroids (Fukushima and Rosenfeld).

Each chapter, of average length 50 pages, refers to from 150 to 300 original papers. Despite this dense bibliography, the general impression is much more one of successful synthesis than of compilation. This series of careful coherent accounts of major metabolic topics should make the book worth its high price to biochemists engaged in advanced teaching or in research into the topics treated.—R. B. Fisher.

1547

HAMMOND, J. (Ed.) **Progress in the physiology of farm animals. Volume 1.** Butterworths Scientific Publications, London, 1954, pp. vii + 392.

Dr. Hammond is the father of agricultural physiology in this country and the late F. H. A. Marshall the grandfather. Their squirearchy in the School of Agriculture, Cambridge has produced many pupils and their influence is seen throughout the whole Commonwealth. This series, of which only volume I has so far appeared, is edited by Dr. Hammond and is intended to supplement, not to replace, other books dealing with the physiology of farm animals. Animal production is the science of making use of the normal trends of animal life and leading them in a way which is more economical for the farmer. To do this it is essential to understand the basic biological processes of life; in other words, to study their physiology, using that word in its broadest sense. The agriculturist is therefore most interested in long-term effects on the animal and so departs from the usual concept of physiology, which is concerned more and more with the intimate detail of cellular reactions.

Volume 1 deals with nutrition and environment. Nutrition is a tedious subject if it amounts to nothing more than determining how many pounds of this or that or how many milligrams of the several vitamins are needed to make an animal increase weight at such and such a rate. The chapter on poultry can be criticised in that too much attention is given to such information, while the really interesting peculiarities of the digestion and metabolism of the bird are but cursorily treated. A more complete bibliography to this chapter would have been welcome.

Nutrition, however, is not necessarily a tedious subject and the chapters on ruminant nutrition and trace elements show what can be done when they are treated against a biological background. It is true that in the chapter dealing with ruminants some assumptions are made from the available evidence that are scarcely warranted, such as that

60 per cent. of the protein of the ration is converted to bacterial protein. These will be put right in the course of time; otherwise the chapter makes interesting reading. The chapter on pigs gives a stimulating account of the growth and nutrition of piglets and shows that the pig is worth studying as a mammalian type quite apart from its final destiny. On this account it is a pity that nothing is said of the alimentary physiology of the pig. Perhaps it is not necessary if one believes that the only interest to be found in pigs lies in the ultimate bacon. The whole section on nutrition is meant to include metabolism, but one cannot but be struck by how little is known (or is mentioned) of metabolism in farm animals.

The section dealing with environment starts with an interesting account of the ecology of farm animals. This is a sadly neglected subject and the chapter is a welcome addition to a book on physiology; it is also an indication of the breadth of perception of the editor. The environmental physiology of domestic animals and of poultry is treated with precision; work on this subject is mostly pre-occupied with measuring the overall reactions of animals and birds in terms of heat losses and the different indications of heat tolerance under different environmental conditions. Housing inevitably comes into consideration. It seems as though this period is now coming to an end and that more attention will in the future be given to the essential nervous and vascular reactions concerned with temperature control. A start on these lines has been made with cattle. The chapter dealing with poultry ends with a provocative discussion on the merits of poultry and reptiles as egg producers in tropical climates, a subject worth some thought. The section ends with a chapter on the effect of daylight changes on the breeding cycle, which is perhaps the nearest approach to classical physiology in the whole book; maybe this is because the stamp of F. H. A. Marshall, who pioneered this subject, is still upon it.

This is a stimulating and important book, for it will influence the thinking of future generations. Of course criticism can and should be made: the most obvious is that the section on nutrition contains little physiology. Perhaps the most worrying feature of the book is that it reveals the conflict between those who think solely in terms of animal production and those who adhere to a physiological approach.

Marshall was a physiologist primarily; Hammond is a physiologist who has turned his knowledge to good account in terms of animal production. The question this book raises is whether the physiological tradition of the Cambridge School will be followed in the future or whether the next generation will concentrate like Shylock on its pound of flesh.—A. T. Phillipson.

1548
JANČÁŘEK, A. Úvod do fyziologie trávení hospodářských zvířat. [Introduction to the physiology of digestion in domestic animals.] Státní zemědělské Nakladatelství, Prague, 1954, pp. 116.

1549
STURKIE, P. D. *Avian physiology*. Comstock Publishing Associates (Cornell University Press), Ithaca, N.Y., 1954, pp. xx + 423. Price 48s. net.

This book is needed. The author in his preface says that it "should be of especial interest to teachers, students, and research workers in poultry science and husbandry and in veterinary medicine". As the first book devoted to the physiology of birds it will be welcomed by all these and also by zoologists. The author has managed to combine a direct enough approach for the student with the presentation of sufficient detail to supply the research worker with background information, a somewhat rare achievement, and there is an adequate bibliography after each chapter.

The bird has been neglected, and this is soon apparent, for every chapter reveals the width of our ignorance of successive aspects of its physiology. A certain lack of balance betrays the fact that some of these aspects have been more attractive to the research worker than others. The first 2 chapters deal with the physical, histological and chemical characteristics of the blood, the next 3 with circulation, the heart and the electrocardiogram, and in all of these Dr. Sturkie is on his own ground. Respiration and the regulation of body temperature follow, and a short chapter on energy metabolism. The digestive tract has been fairly well studied. There is a chapter on carbohydrate metabolism, but protein and mineral metabolism seem to have received scant notice. Apart from short sections on the special senses, too, the central nervous system is hardly mentioned, and behaviour not at all. Not unexpectedly, because of their practical importance, reproduction and egg formation are relatively well understood, especially in the domesticated species. The book ends with several short chapters on the endocrine organs.

With such a wealth of information, it is unfortunate that the presentation is marred for the British reader by the ugly and often ungrammatical phraseology and the constant use of jargon. The book is pleasant to handle and type and paper are good. The illustrations are not memorable. There are too many misprints. The spelling "granivorous" appears several times, and "graniferous" on p. 193 is almost inexcusable.

D. Duncan.

1550
SACKS, J. *Isotopic tracers in biochemistry and physiology*. McGraw-Hill Book Company, Inc., New York, 1953, 1st ed., pp. vii + 383. Price 68s.

The number of textbooks dealing with the applications of isotopes to biochemical and physiological problems is now reasonably large, but this monograph by Professor Sacks will be regarded as a worthy addition to the list.

The chapters in the book can be divided into two sections. The first deals with the general principles of the use of tracers as tools in biological experiments and discusses such matters as the limitations of the technique, methods of measurement, the general design of tracer experiments, and the precautions which are essential if the hazards to health are to be minimised. This section which comprises the first six chapters is followed by ten chapters describing some of the results which have been obtained when isotopic tracers have been used in the investigation of metabolic pathways and of such topics as ion transport and the physiology of the blood. These chapters may perhaps give the uninstructed reader a wrong impression of certain aspects of biochemistry and physiology. Naturally enough no mention is made of the not inconsiderable contributions made by non-isotopic experimental work, but this tends to give the impression that our knowledge of the metabolism of carbohydrate, fat, protein, and other nutrients, has been built up solely by the use of the tracer technique. Moreover, the work described and the references given are almost entirely American. If it is remembered that these chapters provide merely examples of the use of isotopes in biological research and are in no way an account of the development of present knowledge in particular fields, then they do serve a useful purpose. At the same time one cannot help wishing that Professor Sacks had expanded the chapters on general methods at the expense of those giving examples of applications.

The whole book is characterised by its great lucidity and the author, commendably, draws attention at all times to the necessity for careful design of experiment and, even more important, careful interpretation of the results. The publishers too are to be congratulated on the excellent standard of production. The book is printed in pleasant type on good quality paper, and is strongly bound.—W. C. Hutchison.

1551
LEDERER, E. and LEDERER, M. *Chromatography. A review of principles and applications*. Elsevier Publishing Co., Amsterdam, 1954, pp. xviii + 460. Price 60s.

The field of application of chromatography

N.A. and B., January 1955

methods has so greatly expanded in the last 10 years that any review of the subject is of interest. Of the numerous books on chromatography which have been published recently this is by far the most comprehensive. It reviews all types of chromatography, dealing briefly with the general theoretical and practical aspects of the subject and exhaustively with applications of the methods. As such a wide field is covered there is insufficient space, in a book of reasonable dimensions, for much detail of all the individual applications, but a surprising amount of detailed information is presented on many of the topics and the literature has been exhaustively surveyed. The intention to keep abreast of the continuing expansion of the field is shown in an appendix containing a classified list of papers which have appeared too recently for review in the present edition.

The book is on the whole uncritical, and this is a pity as regards the theoretical treatment of chromatography. For the rest, the vast scope of the subject precludes any one author or pair of authors having sufficiently broad experience to attempt criticism except in a narrow sector.

The main value of the book will lie in its quality as a reference book. In this capacity it should prove of great value in any laboratory with biochemical or chemical interests.—G. Leaf.

1554

ECKEY, E. W. (with MILLER, L. P.) *Vegetable fats and oils. Reinhold Publishing Corporation, New York, 1954, Amer. Chem. Soc., Monograph Ser. No. 123, pp. ix + 836.*

This work carries the same title as its now out-of-print predecessor in the same series. The present author has rewritten the book, but it remains a descriptive catalogue of the chemical properties of vegetable fats and oils. The old "technological" order of classification into drying, semi-drying and non-drying oils has been replaced by re-grouping them on systematic botanical lines according to the plant of origin. In addition to many photographs, the text is liberally supplemented with tables showing the analytical characteristics of the lipids of related plants, thus facilitating ready comparison.

Vol. 26, No. 1

By way of preface to the main part of the book are 7 chapters covering the chemical composition and physical properties of fats in general, their nutritional and biochemical significance, their biogenesis and methods of analysis.

References are indicated in the text and given in full at the end of each chapter; a comprehensive subject index (occupying no less than 46 pages) is provided.

This compendious volume, which is well produced and strongly bound, should prove a valuable work of reference.—G. A. Garton.

1555

CÉPÈDE, M. and LENGELLÉ, M. *Économie alimentaire du globe. [World food economy.] Librairie de Médecis, 3 Rue de Médecis, Paris, 1953, pp. 654. Price 47s. 6d. net.*

This large-scale work, in four parts, grew out of a study by Lengellé of the relation between fat consumption and energy consumption and one by Cépède on the relation between consumption of animal products and energy consumption, based on data from the F.A.O. World Food Survey, mainly for the years 1934-38. Mean consumptions of fat, sugar, meat, milk, pulses, cereals and roots and tubers, and the proportions of the total energy supplied by them, are tabulated for daily energy consumptions per head from 1800 to 3200 Cal. by 200 Cal. stages, and these are used as standards of reference for the discussion and graphical presentation of the food habits of different countries and regions of the world. Part 1 closes with a brief geographical survey indicating the countries with diets which are either inadequate or unbalanced, or both.

The evil results for health, physique and mortality are elaborated in part 2, with statistics for many countries, notably from France during the second world war. Two concluding chapters, more speculative but of gloomy interest, with quotations from classical and early Christian literature onwards, are devoted to the psychological effects of underfeeding and the part they may play, when conjoined with the contrast between "haves" and "have nots" among classes and nations, in bringing about revolution and war.

Part 3 is devoted to economic aspects of food. Among the topics considered are the relation between food expenditure and standard of living, the effect of nutrition on productivity in industrialised countries and colonial regions, the problem of animal versus crop production, seasonal variations in food supply, and the general world food situation.

The final part deals with world food policy. After an account of trends in world food trade and special consideration of the fat problem both of the world in general and France in particular, and of

the problems of animal production in France, food plans for underdeveloped countries, in particular those of the French overseas territories, are discussed. There is a chapter on the possibilities and limitations of international aid and finally, a chapter emphasising the precarious food position under present economic circumstances of Western Europe, and the necessity that she should develop a coherent food policy, both for her own survival and as a contribution to general human welfare.

To back up the wide range of topics covered there are numerous scientific and literary references, a great many tables and diagrams and 9 coloured maps of the world or parts of it. Other interesting

items are a list of great famines in world history and an appendix on films, commercial and other, dealing with hunger.

Enough has been said to indicate the wide range of subject matter. With such riches it is perhaps inevitable that the treatment should be somewhat uneven and here and there uncritical; for example, aspects of hygiene other than nutrition must have played a part in some of the mortality statistics quoted. One cannot help thinking also that a more compact, less ambitious volume would have been more likely to be read by and to influence those in authority in national and world affairs.

W. M. Deans.

8. FOOD AND AGRICULTURE ORGANIZATION (AND OTHER ORGANIZATIONS) OF THE UNITED NATIONS

Monthly Bulletin of Agricultural Economics and Statistics.
Vol. 3, No. 9, September 1954, pp. 40. Price \$0.50. No. 10, October 1954, pp. 52. Price \$0.50.
Recent developments in the world food and agricultural situation.

Grain exports, by source and destination, 1953-54. Rome, Italy, 1954. Mimeographed, pp. 22. Price \$0.25.

Nutritional Studies No. 1. Rice and rice diets. A nutritional survey. Revised edition. Rome, Italy, September 1954, pp. v. + 78. Price \$0.75.

In this revised edition of the review first published in 1948 (see p. 917, Vol. 18) much of the text remains as in the original. Its being brought up to date is based largely on the results of deliberations at the 2nd and 3rd meetings of the Nutrition Committee for South and East Asia held at Rangoon in 1950 (p. 516, Vol. 20) and at Bandung in 1953 (p. 484, Vol. 24). In the tables in this edition data on mortality rates and on rice consumption and amino-acid composition have been revised and more recent analyses for Indian and Malayan samples have been included. The bibliography with 100 entries is half as large again as that in the original edition.

Nutritional Studies No. 13. Syndrome policarencial infantil (kwashiorkor) and its prevention in Central America. Rome, Italy, October 1954, pp. v. + 81. Price \$1.00.

Following a recommendation in 1951 by the Joint FAO/WHO Expert Committee on Nutrition a study of the relevant South American literature was made and later brief visits were paid to Guatemala, Honduras, Nicaragua, Costa Rica and Panama. As a name for the disease, which is essentially the same as kwashiorkor in Africa,

the authors have chosen one which is coming into general use from among at least 15 which have been applied locally to the condition.

The medical aspects are considered in 6 categories of changes in general health, digestive system, metabolism, skin and mucous membranes, cardiovascular and haematopoietic systems and in bone and muscle. Complete data on its incidence are not available, but it appears most often at between 1 and 4 years of age. There was some evidence of its being more frequent at over 5 years of age than is kwashiorkor in Africa.

Weaning practices, often from breast milk to maize gruel, are described. From diet surveys which had been made in 3 of the territories, Guatemala, Honduras and Costa Rica, it was found that protein intake, while probably adequate in amount, was poor in quality with only between 7 and 17 g. per head daily from animal sources, and that intakes of calcium, vitamin A and riboflavin were below recommended amounts. Ignorance amongst mothers of the relative values of foods does much to prevent the best use being made of those that are available.

For the prevention of the disease a long-term measure is increasing the production of foods rich in protein. Of these milk is the most important and the area is fortunate in not being beset with problems of overstocking and erosion. Equally far-reaching are the educational and hygienic measures which must be pressed forward to take the place of the short-term programmes in supplementary feeding at present being financed by UNICEF.

Subjects mentioned as awaiting further investigation are, the effect of infections in precipitating the appearance of the syndrome, diet surveys for individual children, the incidence of the disease among negro children in the area and, in the technological field, the preparation of simple and cheap mixtures for the feeding of babies and young children.

THE RELATION OF LACTOSE TO CALCIUM METABOLISM	312	REFERENCES	319

Introduction

THE only known source of lactose in nature is the milk of mammals; it is found in the milk of every species which has been studied, in amounts usually ranging from 2.0 to 8.5 per cent. As the natural carbohydrate food of every infant mammal it might be expected to hold a special place in paediatric practice, yet only a few writers on the subject have given it much attention, and opinions about its value differ greatly. Examination of the literature reveals that lactose has physiological effects not characteristic of other sugars or even of other disaccharides; some of them are due to galactose liberated when lactose is hydrolysed, others are specific to the lactose molecule itself. Certain of these effects appear to merit more attention than they have hitherto received, and the intention here is to collate the information available and to give expression to some of the questions it evokes.

The ordinary lactose of commerce is α -lactose hydrate, a galactosyl glucose, 4-O- β -D-galactosyl- α -D-glucose monohydrate, $C_{12}H_{22}O_{11} \cdot H_2O$. From lactose solutions crystallised at a temperature above 93.5° C. is obtained β -lactose, 4- β -D-galactosyl- β -D-glucose anhydride. In milk and after being kept in solutions α - and β -lactose form equilibrium mixtures. The physical and chemical properties and industrial uses of lactose have been reviewed by Whittier (1944) and its early chemical history by Funck (1948).

Vol. 25, No. 2

Lactose in the digestive tract

IN the presence of lactases, in dilute solutions of strong acids or emulsin obtained from almonds, lactose is hydrolysed, each molecule giving one molecule of glucose and one of galactose. It can be fermented by yeasts and bacteria with production of lactic acid. There are thus three possible fates in the digestive tract: direct absorption, hydrolysis by alimentary lactase and absorption as glucose and galactose, or fermentation by bacteria.

Plimmer (1907) reviewed some early studies of the occurrence of lactase in the intestine, and concluded that "Of the mammals, the carnivora and omnivora have lactase present during the whole of their lives, but the herbivora only when they are young . . . the ferment . . . is localised in the cells of the mucous membrane of the intestine . . .". Cajori (1935) confirmed in dogs that almost all the lactase activity of the intestine is intracellular. Hydrolysis of lactose therefore occurs during transit from the intestine.

The evidence in regard to the changes with age in lactase activity has not been entirely conclusive. Koehler and Allen (1934) said "Textbooks frequently state that lactase is present during infancy, but disappears, particularly in man, during later life. Evidence on this latter point, however, to our knowledge is very meager." To go further, there is considerable evidence that lactase activity persists in adult man. Folin and Berglund (1922) recovered considerably more galactose than lactose

in the urine of adult subjects who had taken lactose. Watkins (1928) found that women, especially during menstruation and in pregnancy, could take quite large doses of lactose without excreting any sugar, the implication being that it was hydrolysed and utilised and not excreted. In men, and in women during the intermenstrual phase, ingestion of 10 g. lactose usually resulted in the appearance of some reducing sugar, either lactose or galactose, in the urine. The sugar excreted by Winter's (1931) female subjects was galactose only. During menstruation tolerance often rose to 20 g. and in pregnancy it was as high as 30 g., but immediately after delivery it fell again to 10 g. There is no evidence that ingested lactose or galactose is used as a source of lactose during milk secretion.

While hydrolysis of lactose by intestinal lactase undoubtedly occurs, transfer of lactose from intestine to blood can occur without hydrolysis. As mentioned above, Folin and Berglund (1922) showed that when adult men took 30 g. or more lactose by mouth, lactose appeared in the urine, thus giving evidence that the rate of absorption of lactose easily exceeded the capacity of the intracellular enzyme to hydrolyse it, so that some lactose entered the circulation unchanged. Bray *et al.* (1952), too, found lactose in the urine of a child given lactose by mouth. Verzár and MacDougall (1936), who imply by the term "absorption" passage from the intestinal lumen into the blood, state baldly that "Lactose is especially slowly absorbed . . . *since* [reviewer's italics] it is very slowly broken down"; yet they admit that lactose appears in both blood and urine after consumption of large doses. As lactose can be absorbed without hydrolysis it is difficult to see how the rate of hydrolysis can affect absorption, though the products of phosphorylation are probably absorbed more quickly than lactose itself. The transfer of lactose across the wall of loops of small intestine *in vitro* does not seem to have been studied.

Whatever the reason, lactose does seem to be absorbed slowly, since a proportion of the lactose ingested usually escapes absorption in the small intestine and reaches the colon. Although an excess of lactose causes diarrhoea in all species of animal, absorption is not limited solely as a result of increased intestinal motility. Feldberg and Solandt (1942) found that lactose had no stimulating effect on the motility of the isolated small intestine *in vitro*, but Fischer and Sutton (1948) demonstrated that diets containing 20, 30 or 40 per cent. lactose on dry basis passed through the digestive tract of rats more rapidly than similar diets with the lactose replaced by maize starch. The diet with 30 per cent. lactose had most effect on motility and that with 40 per cent. the least effect, but the latter caused the most severe diarrhoea.

The fairly extensive literature relating to lactose diarrhoea was reviewed by Fischer and Sutton (1949). When only moderate amounts of lactose are given the diarrhoea is transient and adaptation occurs in a few weeks, but with excessive amounts adaptation does not occur. Fischer *et al.* (1949) were unable to correlate adaptation in rats with any increase in intestinal lactase activity, but there is a relation between adaptation and the rate of absorption when the latter is expressed as the rate of disappearance of lactose from the gastro-intestinal tract. When rats were given lactose solution and killed an hour later, more lactose had been absorbed by adapted than by unadapted animals (Fischer and Sutton, 1953). Thus the rate of absorption depends on some factor other than lactase activity or intestinal motility.

Since most of the information available about the effect of lactose on the intestinal flora is closely related to work on infant feeding it will be considered in that context.

Lactose in the body

The effects of sugars given parenterally were quite widely studied at the end of the nineteenth century. Pavy (1899) injected sugars intravenously and subcutaneously into rabbits at rates of from 1 to 4 g. per kg. bodyweight. He reported that both sucrose and lactose "seem to comport themselves within the general system as unserviceable foreign matter and become speedily cast out in the urine". No physiological effect was observed. Folin and Berglund (1922) found no evidence of a renal threshold for lactose or galactose. Winter (1931), too, found that lactose given by vein to rabbits, even when they were lactating, was "largely" excreted unchanged in the urine. In rabbits with nephritis induced by tartrate, removal of injected lactose from the blood was slow, again suggesting that it is metabolised with difficulty and mostly excreted (Corley, 1929). Yet Hogan (1914) observed that "the recovery of sucrose or lactose in the urine after parenteral introduction of these sugars has frequently not been quantitatively complete". In experiments with dogs recoveries from 1 g. lactose given subcutaneously were usually from 60 to 90 per cent., though "on half a dozen occasions little or none was recovered". Hogan also quotes Leopold and von Reuss (1909), who gave repeated subcutaneous injections of lactose to dogs and children and estimated recoveries of "sugar" in the urine. Many results showed that 1 g. lactose might be completely retained by dogs weighing 4 kg., and one dog of 20 kg. retained 6 g. Similar results were obtained with children. Normal and diabetic adults retained from 2 to 10 per cent. of lactose given intravenously (Koehler *et al.*, 1935).

The explanation of this retention may lie in the report of Cajori (1935) that liver tissue and water extracts of live tissue from adult dogs showed some lactase activity, which "may be of significance in revealing a further mechanism for lactose hydrolysis in the body". There is no such information about the human liver, but the results described above suggest that it also may have some lactase.

Although the amount of lactose hydrolysed in the liver is probably insignificant, it may be true that the amount of lactose excreted in the urine after ingestion of lactose is not a guide to the amount absorbed intact. There is no biochemical evidence that lactose can be metabolised in the body without hydrolysis. What, then, is the nature of the effects attributed to it?

Blanco (1928) gave lactose intravenously and subcutaneously to rabbits anaesthetised with amylal and obtained increases, not only of total blood sugar, but also of blood glucose. In one rabbit the increase in total sugar 30 minutes after the injection was more than the amount of lactose injected. These results suggested that lactose might have caused mobilisation of glucose. Galactose and xylose also increased blood glucose, so the effect was not specific. On the other hand, lactose given by mouth to children depressed the blood glucose level, although an increase in blood galactose accounted for a small increase in total sugar, which was considered to follow from an improvement of glucose utilisation in the presence of galactose (Orsini and Pandolfelli, 1950). Normal adults showed no increase of blood sugar after ingestion of 80 to 120 g. lactose, though lactose or possibly galactose often appeared in the urine, incidentally supporting the observation of Folin and Berglund (1922) that there is no renal threshold for these sugars (Koehler *et al.*, 1935). In diabetics the blood fermentable sugar rose after lactose ingestion, and the urine contained fermentable sugar but no lactose. Since the diabetics dealt normally with injected lactose, it is postulated that no lactose was absorbed by them without hydrolysis, although in normal subjects some may have been absorbed unchanged. In experiments of Winter (1931) women given lactose by mouth excreted galactose but no lactose. As indicated by its effect on total blood sugar and its excretion in the urine, lactose was better utilised by subjects aged from 10 to 89 years than was dextrose, though less well than invert sugar or fructose (Albanese *et al.*, 1954).

Since most of the lactose absorbed by normal adults appears to be hydrolysed, many of the effects of dietary lactose may be ascribed to glucose or to galactose or to the specific value of these two sugars when utilised together. Lactose appears to give rise to a quite characteristic type

of body composition. One of the important effects of lactose feeding seems to lie in the amount of fat deposited. Jarvis (1930) records that fat babies were rare among those receiving diluted cow's milk with lactose; he remarked on the firmness of their tissues, as did Gerstley *et al.* (1945). Whittier *et al.* (1935) noted that young rats receiving 30 per cent. of the dry matter of the diet as lactose grew better than those receiving sucrose, and when they were adult they ate less, contained less fat and tended to live longer. Similarly, rats receiving 27 or 37 per cent. lactose had small livers containing less fat, and especially less non-phospholipin fatty acids, than those given other sugars, even when the diet contained 25 per cent. fat (Artom and Fishman, 1947). The similarity between these effects and those of a choline supplement is obvious and suggests that lactose led to extra production of choline, either by the tissues or by the intestinal flora. Such an effect was obtained also in pigeons after 4 weeks on a wheat diet with 1 g. lactose daily (Sadhu, 1953). Besides the low fat and phospholipin in the liver, the birds had high cerebroside and phospholipin and low sphingomyelin contents in the brain tissue. Sadhu speaks of a "choline-sparing" effect of galactose, suggesting that in the brain sphingosine can take up galactose or glucose to form cerebroside or else choline phosphoric acid to form sphingomyelin. He reported a positive correlation between the cerebroside and sphingomyelin contents of the brain and the lactose content of the milk of several mammalian species (Sadhu, 1948; 1952).

The alternative fates of galactose in the body are not well understood. Besides its role in the formation of cerebroside and mucopolysaccharides it appears to be oxidised in the liver. But Wick and Drury (1954) report that although galactose can enter the extrahepatic cells of the body slowly, and its entry can be accelerated by insulin, yet "the intracellular enzyme system has little if any capacity to oxidise galactose" as it oxidises glucose or mannose. Some support is thus given to Fournier's distinction (see p. 313) between "structural" and "energetic" sugars.

The interaction between lactose and dietary fat will be dealt with in the section on lactose tolerance. In rats galactose or lactose produced more liver and muscle glycogen than did glucose alone (Deuel *et al.*, 1933; Coryell and Christman, 1943).

Calves reared on synthetic milk diets containing lactose gained in 31 days twice as much weight as when glucose or maize syrup was the carbohydrate source. Ten per cent. of lactose in the dry matter of the rations containing other carbohydrates improved their utilisation (Flipse *et al.*, 1950a, b). Lactose tended to maintain normal faeces when the other sugars caused diarrhoea.

The relation of lactose to calcium metabolism

The relation to calcium metabolism may well be one of the most important aspects of lactose metabolism, but it has been the object of sporadic observations only and merits closer attention.

The first reference to a relation between lactose and calcium metabolism appears to be that of Bonnamour *et al.* (1913). A single adult rabbit was subjected to intravenous injection of 10 g. lactose every second day until 378 g. had been given. The animal at first appeared little affected, and maintained its weight without significant loss. After 2 months its bones began to soften, and when it was killed the skeleton was found to be soft, with slender, translucent ribs showing recent fractures, and the femurs curved in an arc. Analysis of the femurs revealed loss of calcium, with magnesium, phosphorus and total ash all above normal, on a dry matter basis. We have no information about what this rabbit ate or whether it was exposed to sunshine.

Yamane (1932) gave cane sugar to rabbits by mouth or intravenously and obtained softening of the bones; the calcium and phosphorus content of the bones decreased, but the calcium : phosphorus ratio was unchanged. Handler (1947), finding that rats given high lactose diets excreted much calcium in the urine, sought to check Bonnamour's results. His rats had a mineral mixture, vitamin mixture and cod liver oil adequate for their usual needs. He injected 0.5 g. daily of several sugars intraperitoneally; after 2 months the femurs of rats which received lactose or galactose weighed slightly less than those of rats having other sugars, but the concentrations of calcium and phosphorus and the ratio between them were not significantly different. The interpretation to be placed on these conflicting reports remains in doubt.

Equally dramatic was the work of Dragstedt and Peacock (1923). Believing parathyroid tetany to be due to a toxin, probably absorbed from the gut, they studied the effects of diet on the survival of dogs after removal of the parathyroids. Dogs on ordinary diets survived 3 to 5 days, but when they were given lactose puppies survived up to 10 days and adult dogs sometimes more than a year, and the incidence and severity of tetany were much reduced. Inouye (1924) repeated these experiments with purified diets. With a diet containing 5.5 per cent. casein, 5 per cent. lactose on dry matter basis, given at the expense of sucrose, was insufficient, but 15 per cent. lactose prevented tetany; with 37.6 per cent. casein, 35 per cent. lactose was necessary, or 20 per cent. galactose. Dextrin was not effective. In attacks of tetany lactose alone had some beneficial effect, but not as much as injected calcium. When calcium lactate given by mouth failed to raise the serum calcium

level, calcium lactate with lactose succeeded. When dogs received a diet containing 5.5 per cent. casein and 68 per cent. sucrose, with butterfat and a mineral mixture, 6 g. lactose (2 dogs) or 4 g. galactose (2 dogs) per kg. bodyweight, injected subcutaneously, failed to prevent tetany. The mineral mixture provided 0.25 g. calcium lactate and 2.3 g. bone ash per 100 g. of food, but ample calcium must be present for lactose to exert its effect. The importance of calcium was stressed by Salvesen (1923). After parathyroid removal dogs could be maintained alive by repeated injections of calcium, but nearly always tetany occurred within 24 hours after the last injection. With a milk diet the calcium injections could be reduced and omitted after a few weeks and the dogs lived indefinitely, although their serum calcium often remained at levels of about 5 or 6 mg. per 100 ml. When calcium was removed from the milk by adding oxalate and centrifuging, the milk diet was useless.

McCullagh and McCullagh (1932) used lactose diets to treat parathyroid tetany in human patients and obtained good results. In one patient neither parathyroid extract nor calcium lactate would relieve tetany, but both together, or calcium lactate and lactose, were successful. In three others calcium lactate and lactose together gave prolonged freedom from tetany after calcium alone had failed. Galactose did not relieve tetany.

In weaned calves, lactose given with an ordinary diet sometimes caused an unexpected fall of serum calcium, with a rise of phosphorus, but lactose given with calcium lactate produced a sharp rise of serum calcium and fall of phosphorus (Robinson *et al.*, 1929). Twice as much calcium was retained with lactose as when bonemeal or calcium lactate was given alone.

What is the mechanism of this effect of lactose? Bergeim (1926) found that in rats the addition of 25 per cent. lactose to the diet on a dry matter basis increased retention of calcium and sometimes of phosphorus, whether or not cod liver oil was given; "There does not appear to be any other reasonable explanation . . . than that of the increased acidity of the intestinal contents". Outhouse *et al.* (1935) also gave 25 per cent. lactose, which induced in their rats about the same phosphorus retention as did cod liver oil, a somewhat smaller calcium retention and "startlingly more" of magnesium. The effect was not due, as Bergeim suggested, to a more acid intestinal medium; lactose reduced intestinal pH in rats on a vegetable diet, but not in those receiving meat, and yet calcium retention was improved (Robinson and Duncan, 1931). Lactose *in vitro* combines with either Ca^{++} or Mg^{++} ions to form soluble, non-ionised compounds (Nordbø, 1939), and forms also salt complexes such as

lactose. $\text{CaCl}_2 \cdot 7\text{H}_2\text{O}$, which are more soluble than lactose itself (Jensen *et al.*, 1940). It might be thought that formation of such complexes would assist calcium absorption, but when rats were given calcium lactate in water or in sugar solutions, neither 5 nor 20 per cent. of lactose increased the rate of calcium absorption, and the higher concentration may even have been inhibitory (Roberts and Christman, 1942).

In children liberally supplied with vitamin D, 36 g. lactose given daily increased calcium retentions by from 7 to 89 per cent. above those found before lactose was given, and an effect persisted for some time after the lactose was withdrawn (Mills *et al.*, 1940). These children excreted significantly less calcium in the urine while taking lactose, on the average 12.0 instead of 16.9 per cent. of the intake, which is taken by the authors as evidence against increase of absorption. With the work of Roberts and Christman (1942) also in mind it seems reasonable to accept the suggestion of Mills *et al.*, that "lactose exerts its effect, not by rendering the dietary calcium more absorbable in the intestinal tract, but by making more utilizable that calcium which had found its way into the blood stream". Such an explanation would account also for the value of lactose feeding combined with injected calcium in tetany (McCullagh and McCullagh, 1932). Simultaneous injection of lactose and calcium does not seem to have been tried.

Its high lactose content may partly explain the value of human milk in the prevention of rickets: "The incidence of rickets among infants fed on human milk is everywhere decidedly less than that of those brought up on cow's milk" (Hess and Weinstock, 1927; see also Kline *et al.*, 1932; Gerstley *et al.*, 1945). In chicks lactose gave higher bone ash than ultraviolet irradiation with otherwise rickets-producing diets, though irradiation sufficed to prevent rickets (Kline *et al.*, 1932). Lactose protected young rats against rickets only less effectively than did cod liver oil, but failed to heal existing rickets (Sunderlin, 1933). The bones of rats on lactose had more ash than those on starch and sucrose, but galactose did not increase bone ash (Outhouse *et al.*, 1937). In later experiments cod liver oil increased retention of both calcium and phosphorus, lactose affected only calcium (Outhouse *et al.*, 1938). However, H. H. Mitchell *et al.* (1937) found higher percentages of ash, calcium and phosphorus in lactose-fed rats than in those fed on other sugars. More calcium was retained by the former in spite of diarrhoea and the lower digestibility of the diet. Increased utilisation of calcium occurred in growing rats and dogs, but not in mature animals (French and Cowgill, 1937).

A diet of whole milk (but not one of skimmed milk), when supplemented with the necessary trace

elements copper, iron and manganese, had effects similar to those of synthetic diets containing lactose. Rats given supplemented milk alone grew to a good size, but never became fat. They had denser bones and more calcium per unit body volume at the age of natural death, although their calcium intake had been only about half that of rats on stock diets (McCay *et al.*, 1952).

On the relationship of lactose to calcium metabolism important work has been done recently in France. Fournier (1954b) found with rats that diets containing not only lactose, but also D- and L-xylose and D- and L-arabinose each doubled the coefficient of utilisation of dietary calcium when compared with a diet in which starch was the only carbohydrate. Sucrose, glucose and maltose gave no better results than starch. Fournier considered lactose, galactose, xylose and arabinose as "structural" carbohydrates, the others as "energetic", by which he suggests a concept new in carbohydrate physiology. Diets composed mainly of milk (Fournier *et al.*, 1953) or containing 12 per cent. lactose on dry basis (Fournier, 1954a) partly or completely prevented loss of skeletal weight in lactating female rats. A group of rats on a stock diet lost on the average 250 mg. calcium from their bodies in the course of a lactation; those receiving the same diet with 12 per cent. lactose replacing starch gained on the average 18 mg. calcium during the same time. The suggestion is made that there may be some participation of lactose in the function of the bone cell. At all events, the evidence is that its relation to calcium metabolism is specific to the lactose molecule. If so, the relatively small amounts which are absorbed unchanged must be responsible. If the effects of lactose on the serum calcium in tetany as well as those on bone composition be taken into account, a wider concept of its role than that suggested by Fournier emerges, namely, the possibility that lactose can take part in the biochemical processes fundamentally concerned in calcium metabolism. There is, indeed, some resemblance between the effects of lactose and those of the parathyroid hormone (Campbell and Turner, 1942).

Another possible effect of lactose is submitted tentatively for consideration; the part it plays in the treatment of milk fever in cattle. The resemblance of certain elements of the milk fever syndrome to parathyroid tetany has led to the concept that milk fever is due at least in part to parathyroid hypofunction (Green, 1939), and parathyroid extract has, in fact, been used in its treatment. The old and usually effective treatment was by inflation of the udder. Inflation has now been to a great extent superseded by injection of a calcium salt, usually calcium borogluconate, but Robertson *et al.* (1948) found that "... in some cases of milk fever and particularly on certain

farms, inflation is a more reliable and more successful form of therapy." Cows which failed to respond to calcium injections responded to subsequent udder inflation. In a later discussion of this work (Robertson, 1949), Dryerre remarked that lactose, a product of mammary gland activity, appeared in the blood after inflation, and that consequently it might be argued that inflation put something else from the udder into the blood which might affect recovery. Lactose was here mentioned only to illustrate the occurrence of reabsorption, but it may now be considered whether lactose itself is not involved in such recoveries.

In his reply to Dryerre in the discussion mentioned above, Robertson stated that the cows were always milked out before udder inflation, and he did not support the theory that it was simply a case of putting constituents back into the blood or of stopping secretion. However, since milk secretion is normally a continuous process, milking out does not remove milk constituents entirely. Colostrum at parturition contains about 2.5 per cent. lactose and one-tenth of this amount of calcium and phosphorus, but 24 hours later the composition is almost that of normal milk, lactose having risen to a mean value (obtained from the results of 25 authors) of 4.23 per cent. and calcium and phosphorus having fallen to 0.15 per cent. or less (Garrett and Overman, 1940); about two-thirds of the calcium is in colloidal form (Ling, 1937). There does not appear to be information on the composition of milk obtained after the udder has been inflated with air, but when milk is returned to the udder after milking its lactose is rapidly re-absorbed (Jackson and Rothera, 1914). Petersen and Rigor (1932) delayed milking and found that "The most striking effect of retention of milk in the udder is upon the lactose content. Lactose rapidly diminished from nearly a normal of 5% to less than 1% for milk retained 120 hours. . . . Total ash increased, reaching the maximum in 36 hours. Calcium and phosphorus, however, decreased, reaching the minimum after 120 hours, which was slightly more than one-half of the normal." The amount of lactose likely to be absorbed, then, is considerably greater than the amounts of calcium or phosphorus; the amount of calcium available is unlikely to be of significance to a cow which has already failed to respond to injected calcium. Owing to the lack of a renal threshold the blood lactose level is not a guide to the quantity absorbed; lactose solutions injected even into the mammary ducts failed to raise significantly the blood sugar, although large quantities of lactose appeared in the urine (Brown *et al.*, 1936). Nevertheless, a mechanism such as that postulated above (p. 313), whereby lactose improves the metabolic use of calcium, may well

be brought into play as a result of udder inflation. Kirillov and Tsarenko (1953) treated cows with milk fever by infusing milk into the udder, though they give no clear explanation of why they did so. The results were excellent; seven cows which received from 450 to 2100 ml. milk by infusion into the teat ducts recovered in from 40 to 180 minutes. Two cows treated by inflation of the udder with air and subcutaneous injection of caffeine took 12 and 18 hours to recover.

The possibility that lactose affects magnesium utilisation has not been investigated, but it may be recalled that rats given lactose retained "startlingly more" magnesium than those given cod liver oil or sucrose (Outhouse *et al.*, 1935).

Lactose in infant feeding and its effects on the intestinal flora

As recently as 1932, Sauer wrote in a discussion about the ideal standard diet for the bottle-fed baby that "It seems paradoxical that no one has tried to enrich evaporated milk dilutions with lactose, the natural sugar occurring in breast milk." In fact, it was only two years earlier that the value of lactose had begun to be recognised. For forty years it had been regarded as a dangerous substance, to be avoided as far as possible. The reason for this attitude lay in the teaching of Finkelstein (1906) and his school, reviews of whose work were made by Schlutz (1912) and Porter and Dunn (1915). Briefly, Finkelstein and several earlier writers believed that lactose or acids caused by its fermentation produced inflammation of the alimentary tract and that the inflamed mucosa allowed undigested food components, including lactose itself, to be absorbed. The damage so caused, instead of infection, was blamed for the fever accompanying gastro-intestinal disturbances. "Lactose especially was the sugar [Finkelstein] feared, so much so that he stated that even minute doses of milk containing its natural carbohydrate were damaging. Babies were injured with lactose, dextrose, lactose salt mixtures, and dextrose alkali or lactose alkali mixtures, given in isotonic, hypertonic, or hypotonic proportions. The injury was considered always to express itself in mellituria and fever, and F. M. Schapps, Leopold and Von Reuss were one in thinking with Finkelstein that lactose was 'exquisitely pyrogenic'." (Porter and Dunn, 1915).

Schapps (1908) and others injected glucose or lactose into infants and reported a subsequent rise of temperature, which led to acceptance of the view that sugars are pyrogenic agents in themselves; the effects could be obtained also with salt solutions, and when Schlutz (1912) and others tried to repeat the lactose experiments no significant rise of temperature was found. Finkelstein

abandoned his theory of the directly pyrogenic effect of lactose, but maintained that it and its fermentation products were responsible for intestinal inflammation and that the fever was caused by disturbed osmotic balance.

Talbot and Hill (1914) and Porter and Dunn (1915) were bold enough to give lactose to babies. Talbot and Hill made metabolism trials with one baby. We are not told the exact form of the diet, except that it contained from 1.5 to 3.0 per cent. milk fat and from 1.6 to 1.8 per cent. protein. With proportions of lactose up to 9.93 g. per 100 ml. the baby thrived. With 14 g. lactose per 100 ml. it had diarrhoea and indigestion and the amount had to be reduced, but still no sugar ever appeared in the stools. Porter and Dunn gave as much as 18½ per cent. lactose to initially malnourished infants, and in quantity up to 225 g. or 54 g. per kg. daily with no ill effect; the theory of lactose toxicity was thus quite disproved, two of the sixteen babies each gaining 1 kg. in 20 days. In both these experiments excess of lactose (14 g. per 100 ml. in Talbot and Hill's infant, 9 to 17 g. in individual infants of Porter and Dunn's series) produced green, watery, acid stools containing lactic, acetic, succinic and butyric acids and causing sore buttocks. Despite the excellent results obtained with moderate amounts of lactose the idea was not dispelled that digestive disturbances arose from fermentation of unabsorbed lactose; this was taught in medical schools and as a result no further attempt was made to use added lactose in artificial feeds for infants during the next 15 years.

Two paradoxes appear not to have been fully appreciated. The first was that breast-fed babies were less susceptible to diarrhoea than those on cow's milk, although human milk contains more lactose. The second was the difference between the acid diarrhoea of lactose excess and the nearly neutral stools of the bottle-fed infant. Both points were dealt with in a series of experiments by Gerstley and his collaborators (1928a, b; 1930a, b). Starting with a comparison of the stools of breast-fed and bottle-fed infants, they found that the latter contained more total volatile acids and less lactic acid and were always more alkaline, the higher total acid being related to greater volume. The total acidity was not related to the lactose intake, since the breast-fed and bottle-fed infants received 7 and 4 g. lactose per 100 ml., respectively. Still bearing in mind the earlier theories, Gerstley was led to think that lactose given in cow's milk might somehow be more readily fermented than that in breast milk. What he found was that when as much as 12 g. of lactose per 100 ml. was added to cow's milk, not only was there no diarrhoea, but the infants did extremely well and their stools had a weight, acidity, and content of lactic

and volatile acids similar to those of breast-fed babies. After its long eclipse, lactose emerged unscathed. By the time Gerstley's first series of papers was completed several more had appeared, equally favourable in their conclusions. Barenberg and Abramson (1930) concluded that up to 12 to 15 per cent. of the diet could safely consist of lactose without causing laxation, and that it was well utilised, no sugar appearing in either urine or faeces. Kopeloff and Cohen (1930) connected the beneficial effect of lactose with maintenance of the natural intestinal flora as seen in the breast-fed infant. Jarvis (1930), reporting on over 1000 infants fed on mixtures of cow's milk, water and lactose, saw no evidence of intolerance. "The tissues of these children seemed more firm than that [*sic*] of the average infant receiving vegetable sugar and resembled that of the breast-fed infant. Fat babies were rarely observed. . . . Weight for weight, infants fed on milk sugar possess correspondingly more living tissue than when an excess of storage of glycogen exists as in the case of infants fed on vegetable sugar. Lactose, therefore, should be the sugar of choice for normal infants."

Sauer (1932) used lactose to enrich diluted evaporated milk, and claimed after using it for 150 infants, some of them premature, that it gave results closely comparable with those given by human milk. Skole (1934) reported that on milk mixtures containing lactose infants showed a freedom from constipation, scurvy and rickets unusual in those on cow's milk alone, less frequent gastro-intestinal disturbances, less diarrhoea and a general improvement in well-being. Moreover, lactose gave excellent results even in babies which had diarrhoea and vomited while breast-fed (Skole, 1933). Litchfield (1944) recorded that during the first 10 days of life infants on Biolac, a proprietary preparation with lactose and added vitamins A, B₁, D and iron, gained weight as rapidly as those on evaporated milk with added dextrin-maltose, although the former provided only 10 or 14 Cal. per fluid ounce and the latter 18.5 to 21 Cal. It is not known whether the lactose was responsible or the vitamins. A satisfactory standard mixture used in a hospital contained per 100 ml. 7.4 g. lactose and 2.8 g. each of fat and protein. When the lactose was increased to 8.2 g. there was greater frequency of stools, which was prevented by reducing the vitamin B₁ content. The infants continued to thrive despite these modifications (Wolman and Borowsky, 1943). When infants fed on a dried milk preparation had 3 per cent. lactose added abruptly to it some of them had diarrhoea and vomiting, but when the supplement was introduced gradually there was no ill effect from 3 or 5 per cent. (Ross and Dawes, 1954).

Gerstley *et al.* (1935) found α - and β -lactose equally effective in reducing intestinal pH and

establishing a Gram-positive flora in human infants, but Robinson and Gilliland (1937) found α -lactose ineffective in rabbits, and Maloyth and Kirmilidis (1939) and Priming and Turkus (1943) reported that it failed to encourage *Lactobacillus bifidus* in infants. Human and cow's milk both have equilibrium mixtures of the two forms (Habild, 1949). Schimansky (1943) pointed out the importance which would attach to the proof that substitution of one isomer of lactose for the other would greatly affect the intestinal flora of the bottle-fed baby, but so far this proof does not seem to have been produced.

Müller (1947) reviewed the history of the use of lactose in infant feeding. He considered that fats which encourage putrefactive bacteria are an important source of gastro-intestinal disturbances in babies given artificial foods. Lactose forms a suitable medium for the "bifidus" flora, and is an "Antibiosstoff" for the putrefactive bacteria. Müller also discussed possible differences in the effects of α - and β -lactose, but Frisell (1951) found that both forms produced moderate increases in the "bifidus" counts of healthy babies, while other bacteria were not affected. Ross and Dawes (1954) added 3 or 5 per cent. lactose to the dried milk food of 18 infants and found that while there was an initial fall in pH of the faeces from an average of 7.7 to one of 5.7, this lowest level was maintained for only two or three days. The lactobacillus counts then fell off and the pH rose again while the extra lactose was still being given. Ross and Dawes suggested that not only lactose, but probably also the "bifidus factor", is necessary for the maintenance of a lactobacillus flora and the resulting low pH. Of course, the "bifidus factor" itself probably contains galactose (Gauhe *et al.*, 1954; Tomarelli *et al.*, 1954).

Platt (1955) speculates about the possible importance of lactose, or more specifically galactose, for the nutrition of infants. He suggests that if, as seems probable, there is no formation of galactose in the human body except in the lactating mammary gland, this sugar may be regarded as a dietary essential because of its role in cerebroside and mucopolysaccharides. If when the supply of galactose is insufficient, it is replaced in such compounds by glucose, he asks whether the differences might not lead in later life to diseases involving these structural substances, such as disseminated sclerosis and collagen diseases. The infant fed on diluted cow's milk with a vegetable sugar certainly receives little galactose. The rare infant without ability to metabolise galactose normally, who develops "idiopathic galactosaemia", can sometimes be brought up on a diet free of this sugar. Townsend *et al.* (1951) discussed the small number of such infants reported in the literature; one of the persistent accompani-

ments of the disorder is mental retardation, but there are as yet no long follow-up studies from which the incidence of later nervous or connective-tissue sequelae might be discovered. Another result is the development of cataract.

The published work discussed above gives an impression that lactose may be distinctly preferable to other sugars for feeding infants. Diarrhoea seems to occur only when the lactose content of the diet is increased too suddenly or when excessive quantities are given. A careful search of the literature has failed to reveal any other basis for its unpopularity with paediatricians. Yet Gunther (1952) has written: "Lactose is not better than sucrose or glucose in the artificial feeding of infants, and we are still without an explanation of why this particular sugar is present in milk. One can only speculate that the formation of lactose is in some way involved in the process of secretion of the fat and protein."

Effects of an excess of lactose

An excess of lactose may be defined according to two different criteria: that of tolerance in its more usual sense, expressing the amount of lactose which can be taken before sugar appears in the urine; and that of the appearance of ill effects such as diarrhoea and retarded growth.

The relation of lactose intake to diarrhoea was discussed in a searching review by Fischer and Sutton (1949), and it is unnecessary to review the same subject again at length. They concluded that young animals are more susceptible to diarrhoea than older ones. In babies, diarrhoea is commonly produced by diets containing from 12 to 19 "per cent." lactose, depending on individual differences, in puppies by 10 to 15 "per cent." and in weanling rats by 20 "per cent." [It is not clear whether all these percentages are on the same basis.] Lactose is of course not pushed beyond this amount in infants, so for normal babies it may be said to be free from ill effect; any diarrhoea is readily overcome by reducing the lactose intake. Fischer and Sutton considered the lactose itself to be responsible for the diarrhoea and they refer to the possibility that it exerts a "hydragogue" effect, though the diarrhoea is not associated with dehydration. Interference with absorption of water may account for it; solutions of lactose given by mouth, whether hypertonic, isotonic or hypotonic, always led to excretion of less urine than did an equal volume of water (Roccuzzo, 1945).

In animal experiments high proportions of lactose have been given. With calves the utilisation of lactose in whole or skimmed milk was highly efficient, only 1.1 to 3.4 per cent. being excreted. When the lactose content of the milk

was doubled, galactose excreted in the urine represented 8 per cent. of the lactose intake. Calves thus utilise effectively a relatively small concentration of lactose, probably less than 10 per cent. on a wet weight basis (Rojas *et al.*, 1948). Growing rats given 37 per cent. of lactose in the dry matter of their diet had only mild diarrhoea and grew almost as well as those on other sugars (Artom and Fishman, 1947). With 45 or 60 per cent. growth was poor (Mitchell, 1927). Utilisation became less efficient when the diet contained 50 per cent. (Riggs and Beaty, 1947). Weanling rats given 73 per cent. lactose as their only source of carbohydrate developed alopecia and survived for only from 5 to 26 days, according to the strain. Older rats survived with the same proportion of lactose somewhat longer (Ershoff and Deuel, 1944). A mixture of galactose and glucose was as quickly fatal to young rats as lactose; the critical proportion of lactose for survival was 60 to 70 per cent. of the dry matter of the diet, that of galactose 30 or 40 per cent. (Handler, 1947). The failure of skeletal calcification, high serum alkaline phosphatase and low phosphorus levels in these rats might all result from simple inanition (Handler *et al.*, 1947). It is doubtful whether these large proportions of sugar should not be considered as pharmacological instead of physiological.

In all the experiments discussed above moderate quantities of components of the vitamin B complex were supplied, but there is evidence that requirements for them may be high when excessively high carbohydrate diets are used (Byerrum and Flokstra, 1951; Yuckin, 1951), which may account, as will be seen, for the close relation between lactose utilisation and the amount and kind of fat in the diet. Schantz *et al.* (1938) record that rats fed on whole milk supplemented with iron, copper and manganese utilised the lactose of the milk completely; with skimmed milk about 9 to 18 per cent. of the lactose was lost in the urine as galactose. Addition of butterfat, lard, vegetable oils, oleic acid, triolein or tripalmitin prevented the loss of galactose, and complete utilisation persisted for a few days after the fat was withdrawn. Butterfat gave somewhat better growth than the other fats, which was later confirmed and the saturated fraction of the fatty acids was found to be responsible (Schantz *et al.*, 1940a, b). In calves, too, butterfat, closely followed by lard and tallow, gave better weight gains and general condition than did vegetable oils; with maize, cottonseed or soya bean oils the calves were unthrifty, listless and emaciated, some had dermatitis and several died (Gullickson *et al.*, 1942). Deuel *et al.* (1944), using a diet containing 70.6 per cent. mineralised skimmed milk powder, saw no difference in growth of rats given butterfat, margarine or vegetable oils, but in later experiments with lactose, survival

was better with butter or margarine than with maize or cottonseed oil (Ershoff and Deuel, 1947). This difference in the value of fats is specifically related to lactose; with other sugars there was no difference in value between maize oil and butterfat. Lactose gave poor growth with maize oil, but with butterfat growth approached that obtained with other sugars (Boutwell *et al.*, 1943a). The difference in value between butterfat and maize oil became greater as the lactose content of the diet increased. As with calves, so with rats, lard and margarines containing mixtures of animal fats were only slightly inferior to butterfat (Boutwell *et al.*, 1943b). When large amounts of vitamin B₁, riboflavin, nicotinic acid, pyridoxine, pantothenic acid, *p*-aminobenzoic acid, inositol, choline and 1 per cent. liver powder were given, maize oil gave nearly as good results as butterfat (Boutwell *et al.*, 1945). It was considered that the butterfat enabled the intestinal flora to synthesise more B vitamins than did maize oil. Supplements of beef liver alone gave better utilisation of lactose diets (Ershoff, 1949), and liver but none of the known vitamins cured dermatitis produced in rats by lactose diets with vegetable oil (Collins *et al.*, 1951).

Gruber (1950) related the value of fat in high-carbohydrate diets to a diminished destruction of vitamin B₁ in the tissues. This vitamin may, on the other hand, be less directly concerned. The growth of lactic acid bacteria is stimulated by certain unsaturated fatty acids such as oleic and linoleic acids, though high levels of these acids are toxic (Williams *et al.*, 1947; Tomarelli *et al.*, 1949). Balakrishnan and Rajagopalan (1952; 1953) found the highest vitamin B₁ contents in the urine, faeces and liver of rats in association with high counts of total and coliform bacteria, but not of lactobacilli, and in rats on lactose diets such conditions were obtained with butterfat and not with coconut or groundnut oils. The details of the relation between carbohydrates, fat and vitamin synthesis cannot be clearly seen at present.

Mitchell and Dodge (1935) first reported the occurrence of cataract in rats on lactose diets. Early lens changes occurred after 3.6, 2.4 and 1.3 weeks in rats on diets containing 30, 50 and 70 per cent. lactose on a dry matter basis, respectively. With 70 per cent. of lactose every rat showed lens changes and from 50 to 68 per cent. developed mature cataracts; the severity was less the later in life the rats were first given the lactose diet. The young rats showed only transient diarrhoea, though their faeces often continued to be soft. All appeared sleek and well nourished, but they were blind. Serum calcium was not high on these diets but the calcium content of the whole eye in rats with mature cataract was double the normal amount. Day (1936) incriminated galactose as

the cause of cataract. The high blood sugar associated with high lactose or galactose intakes was due mainly to galactose (H. S. Mitchell *et al.*, 1937), but there was no specific relation between the blood sugar level and the rate of cataract development. The addition of calcium lactate to a diet with 62 per cent. lactose did not affect the incidence of cataract. Calcium gluconate, and to a greater extent sodium gluconate, added to a diet with 60 per cent. lactose produced more severe diarrhoea and lower blood sugar than lactose alone, and did not produce cataract (Mitchell *et al.*, 1939). It is suggested that the gluconate radical interfered with lactose absorption or hydrolysis. Not only lactose or galactose alone, but skimmed milk diets produced cataract in rats (Cashell and Kon, 1939), though whole milk did not (Daniels and Everson, 1935). Here again the relation with fats and vitamins may be involved. Krewson *et al.* (1939) were unable to produce cataract in rats on skimmed milk, even when it contained 20 per cent. free galactose or 70 per cent. lactose, but with 30 per cent. of the dry matter as galactose every rat developed bilateral cataract. Day (1936) claimed that cataract due to galactose was easily distinguished with the ophthalmoscope from that produced by riboflavin deficiency.

Hörmann (1954) has discussed theories about the pathogenesis of galactose cataract, giving about 70 references to literature on the subject. He was able to prevent cataract in rats consuming 70 per cent. α -lactose or 30 per cent. galactose by repeated injection of cocarboxylase. Without cocarboxylase the rats receiving 70 per cent. α -lactose lived only 12 or 14 days, but cocarboxylase extended their survival to the full experimental period of 100 days. Hörmann concluded that lactose and galactose interfere with carbohydrate breakdown and that this is particularly serious in the lens because of its isolation from the blood stream. The young lens is more susceptible than the old (Mitchell and Cook, 1938). When inhibitors of carbohydrate metabolism were added to Tyrode glucose medium in which were lenses from calves' eyes, all the lenses developed cataracts (Nordmann *et al.*, 1954). The cataracts appeared more quickly with four inhibitors affecting different phases of the anaerobic cycle than with two acting on the citric acid cycle.

The effect of excess lactose in rats appears on the whole to be concerned with their inability to metabolise large amounts of galactose. Similar intolerance to lactose, with liver enlargement and cataract as consequences, occasionally occurs in infants with a congenital inability to metabolise galactose (Bray *et al.*, 1952; Johnson, 1953; Hudson *et al.*, 1954).

Lactose indigestion in chicks has another basis. Chicks receiving more than 10 per cent. lactose in

the dry matter of the diet showed progressively poorer growth and more severe diarrhoea, and the toes became curled outwards (Rutter *et al.*, 1953). Galactose produced a toxic syndrome with convulsions, but no galactose was found in the blood after lactose feeding. It is suggested that lactose was not metabolised; the retarded growth and weakness may represent simple undernutrition. Hamilton and Mitchell (1924) found little lactase in the crop and none in the intestines of chickens. Yet no severe toxic sign was reported by Kline *et al.* (1932) in chicks given diets containing initially 10 per cent. lactose, even though the amount was slowly increased to 40 per cent. by the fourth week, and there is no suggestion that the birds were greatly undernourished, as would be expected if such a high proportion of the diet was not metabolised. These results are not reconcilable, but then lactose is an unnatural sugar for birds.

Summary

Lactose has physiological effects not characteristic of other sugars; some are due to galactose liberated when lactose is hydrolysed, others are specific to the lactose molecule.

Hydrolysis of lactose by lactase occurs during its passage from the intestinal lumen to the blood, but absorption of unhydrolysed lactose occurs also. Part, but not necessarily all, of the lactose absorbed or injected is excreted in the urine.

Lactose in the diet, in the presence of ample calcium, maintains normal serum calcium and prevents tetany after parathyroid removal. It increases retention of dietary calcium, apparently by improving the utilisation of calcium already absorbed, and increases the mineral content of the bones. It prevents loss of minerals from the skeleton of lactating rats. A possible role in the treatment of milk fever is discussed.

As the natural sugar occurring in breast milk lactose appears to have special value in infant feeding, yet it has been unpopular with paediatricians. It helps to maintain the natural intestinal flora seen in the breast-fed infant, and produces healthy, firm-fleshed babies with few gastro-intestinal upsets. When it is hydrolysed it provides the energy-producing sugar glucose and the "structural" sugar galactose, which may be important in the formation of such compounds as cerebrosides and mucopolysaccharides.

Excess of lactose in animal experiments produces diarrhoea and undernutrition. Large amounts of galactose are poorly utilised by animals and lead to the formation of cataracts. There is some evidence that galactose may interfere with the mechanisms for carbohydrate breakdown. Fat and large amounts of B vitamins can counteract the effects of an excessive intake of lactose.

1. TECHNIQUE

CHEMICAL

APPARATUS

1556

- DE VERDIER, C. H. and SjöBERG, C. I. An automatic conductivity bridge for chromatographic analyses. *Acta chem. scand.*, 1954, 8, 1161-1168. [Inst. Med. Chem., Univ. Upsala.]

A description of a modified form of the apparatus used by James *et al.* (*Biochem. J.*, 1951, 49, 293) for chromatographic estimations by the automatic recording of conductivity changes in the column. The apparatus has been successfully applied to the separation of amino-acids, and of peptides and amino-acids containing phosphorus.—A. Hepburn.

1557

- CARAVEL, C., DUCLOZ, J. and GROULADE, J. Dispositif d'alimentation à courant constant pour électrophorèse sur papier. [Apparatus for supplying a constant electric current for electrophoresis on paper.] *Ann. Inst. Pasteur*, 1954, 87, 227-229. *Proc.* [Fac. Sci., Centre Transfusion Sanguine, Grenoble.]

1558

- POTTERAT, M. and ESCHMANN, H. Un nouveau ballon-filtre. [A new filter flask.] *Mitt. Geb. Lebensmittel. Hyg.*, 1954, 45, 329-331. [Lab. Serv. Féd. Hyg. Pub., Berne.] German and English summaries.

A description, with diagram, is given of a flask with a side tube fused on at an angle of 120°, by means of which a transfer of precipitate, *e.g.*, in the authors' method of estimating sugars (Abst. 1568, Vol. 25) can be avoided.—W. M. Deans.

1559

- ANTONINI, F. M. Spettrofotometro a fiamma: costruzione di uno strumento a standard interno. [Flame spectrophotometry: construction of an instrument with an internal standard.] *Sperimentale*, 1953, 103, 305-323. [Clin. Med. Gen., Univ. Florence.]

The importance for clinical purposes of rapid estimation of Ca, Na and K in biological fluids is stressed, but flame spectrophotometers are expensive to buy. The theory of the apparatus is discussed and a full description of its construction, with drawings, is given. It was based on previous British and American research and had an internal standard.—E. M. Hume.

1560

- VALLEE, B. L. Simultaneous determination of sodium, potassium, calcium, magnesium and

strontium by a new multichannel flame-spectrometer. *Nature*, 1954, 174, 1050-1051. [Biophys. Res. Lab., Dept. Med., Peter Bent Brigham Hosp., Boston, Mass.]

ANALYTICAL METHODS

General

1561

- DIECKERT, J. W. and REISER, R. Glass fiber paper impregnated with silicic acid as a new chromatographic tool. *Science*, 1954, 120, 678. [Dept. Biochem. Nutrit., Texas Agric. and Mech. Coll., College Station.]

This material is used when the tests needed for detecting compounds involve the use of drastic conditions. Triglycerides, fatty acids and cholesterol and its esters can be separated by using glass paper, impregnated with silicic acid, with 2 per cent. diethyl ether in *iso*-octane as developing solvent. Sterols are located by spraying one side of the developed chromatogram with Liebermann Burchard reagent and then heating on an electric hotplate with exposed elements; they give pink-red spots on a white background. Carbon compounds can be detected on the same chromatogram by spraying the other side with a mixture of H₂SO₄ and dichromate mixture and heating as before to give grey-black spots on a yellow background.—H. G. Bray.

1562

- HAGDAHL, L. and DANIELSON, C. E. A new paper column for preparative chromatography. *Nature*, 1954, 174, 1062-1063. [Inst. Biochem., Upsala.]

The column consists of a roll of filter paper contained in a polythene tube.—H. G. Bray.

1563

- STÖCKLI, A. Mehrdimensionale Papierchromatographie. [Multi-dimensional paper chromatography.] *Helv. chim. Acta*, 1954, 37, 1581-1585. [Versuchstat. Schweiz. Brauereien, Zürich.]

The partly separated constituents are transferred to a fresh paper for each subsequent development.—H. G. Bray.

1564

- EHRLMANTRAUT, H. C. and WEINSTOCK, A. A simple method of applying the Beckman spectrophotometer to the measurement of paper chromatograms. *Biochim. biophys. Acta*,

1954, **15**, 589-590. [Armour Res. Found., Chicago, Ill.]

Excised stained areas of paper chromatograms are attached to the faces of the cuvettes and readings are taken in the normal way. The optical density of the spots is proportional to the logarithm of the concentration.—H. G. Bray.

1565

WALDMANN-MEYER, H. and LOBO-ONELL, C. Separation and concentration of biologic colloids by cryodialysis. *J. Lab. Clin. Med.*, 1954, **44**, 314-319. [Dept. Urol., Univ. Chile, Santiago.]

Biological fluids are placed in cellophane tubes and suspended in cold air. A solution of crystalloids diffuses out and freezes, and so can be removed.—H. G. Bray.

1566

SULSER, H. Die Mikrobestimmung der Phosphatidbestandteile Inosit, Äthanolamin, Serin und Cholin. 5. Mitteilung über Anwendung der Papierchromatographie auf lebensmittelchemische Probleme. [Micro-estimation of the phosphatide components inositol, ethanolamine, serine and choline. 5th Paper on the use of paper chromatography in problems of food chemistry.] *Mitt. Geb. Lebensmittel. Hyg.*, 1954, **45**, 251-294. [Lab. Eidg. Gesundheitsamt., Berne.] French and English summaries.

For other parts see Title 4538, Vol. 21; *Mitt. Geb. Lebensmittel. Hyg.*, 1953, **44**, 79; Abst. 1610, Vol. 25.

Inositol is estimated with ethylacetate:acetic acid: water (3:1:3) as solvent mixture and 2.5 per cent. methanolic AgNO₃ as detecting agent. The solvent mixture for ethanolamine and serine is *n*-butanol: ethanol: water (80:25.5:60) with ninhydrin as detecting agent. Choline is estimated with *tert*-butanol: methanol: water (4:5:1) as solvent and phosphomolybdate and stannous chloride for detection. Other methods of estimating these compounds are reviewed.—H. G. Bray.

Carbohydrate Constituents

1567

JONES, J. K. N. and PRIDHAM, J. B. A colorimetric estimation of sugars using benzidine. *Biochem. J.*, 1954, **58**, 288-290. [Dept. Chem., Univ. Bristol.]

The method depends on the formation by sugars of an orange-yellow colour with benzidine. The reaction is suitable for the estimation of concentrations of from 20 to 600 µg. per ml. of aldopentoses, methylaldopentoses, aldohexoses, hexuronic acids, methylated sugars and disaccharides; ketoses and amino-sugars cannot be estimated.

H. G. Bray.

1568

POTTERAT, M. and ESCHMANN, H. Application des complexones au dosage des sucres. [Use of complexones in the estimation of sugars.] *Mitt. Geb. Lebensmittel. Hyg.*, 1954, **45**, 312-329. [Lab. Serv. Féd. Hyg. Pub., Berne.] German and English summaries.

A reagent superior to that of Löffl and Schoorl (*Ztschr. Untersuch. Lebensmittel*, 1929, **57**, 566) was devised, incorporating complexone III (ethylenediamine tetra-acetate), which forms a complex with cuprous oxide.—H. G. Bray.

1569

WHISTLER, R. L. On column chromatography of sugars. *Science*, 1954, **120**, 899-900. [Dept. Biochem., Purdue Univ., Lafayette, Ind.]

The following preliminary preparation of chromatographic columns for the separation of carbohydrates of low molecular weight is advised.

Carbon columns are best washed with 1 per cent. HCl to remove basic ash, and then with distilled water. Celite, usually mixed with the charcoal, sometimes dissolves in the developing solution and can be removed from the concentrated effluent by filtration or by evaporating to dryness and redissolving the carbohydrate in water. Columns entirely of charcoal are advantageous. Cellulose columns should be washed with water to reduce the elution of extraneous carbohydrates. It is better to apply pressure at the top of the column than suction at the bottom, which often withdraws part of the solvent, with consequent poor separations. Columns are best packed dry or with a thick slurry.—A. Hepburn.

1570

SOUTAR, T. H. and HAMPTON, E. Structural changes in boiling solutions of sugar with reference to chromatography of carbohydrates. *Nature*, 1954, **174**, 801-802. [Brit. Jute Trade Res. Assoc., Kinnoull Rd., Kingsway West, Dundee.]

It was shown that a structural change in rhamnose and xylose occurs when they are boiled in water for 12 hr.—H. G. Bray.

1571

McCREADY, R. M. and McCOMB, E. A. Quantitative determination of sugars on paper chromatograms by a reflectance method. *Anal. Chem.*, 1954, **26**, 1645-1647. [W. Utilization Res. Branch, Agric. Res. Serv., U.S. Dept. Agric., Albany 6, Calif.]

1572

POGELL, B. M. The quantitative determination of fructose with skatole and hydrochloric acid. *J. Biol. Chem.*, 1954, **211**, 143-147. [Chem.

N.A. and R., April 1955

Sect., Fourth Army Area Med. Lab., Brooke Army Med. Centre, Fort Sam Houston, Tex.]

Fructose was estimated spectrophotometrically from the purple colour produced on reaction with skatole in concentrated HCl. Sugars other than ketoses did not react significantly at the experimental temperature of 37° C. Glucose in molar amounts 5 times that of fructose did not appreciably interfere but with 10 times there was an error of 9 per cent. The recovery of fructose from mouse liver homogenates, oxalated human blood, human sera and urine ranged from 93 to 102 per cent.—A. Hepburn.

1573

BONTING, S. L. **Differential determination of glucose and fructose in microgram quantities.** *Arch. Biochem. Biophys.*, 1954, **52**, 272-279. [Dept. Physiol., Coll. Med., State Univ. Iowa, Iowa City.]

An adaptation of the anthrone method of Morris (Abst. 14, Vol. 18). Fructose is estimated in reaction mixtures which are not heated, and both fructose and glucose in mixtures heated for 10 min. in a boiling-water bath. The procedure is applicable to quantities of 0.2 to 2 μ g. in 25 ml.

H. G. Bray.

1574

STITT, F., FRIEDLANDER, S., LEWIS, H. J. and YOUNG, F. E. **Photometric determination of glucose in presence of fructose.** *Anal. Chem.*, 1954, **26**, 1478-1484. [W. Utilisation Res. Branch, Agric. Res. Serv., U.S. Dept. Agric., Albany, Calif.]

The method depends on the fact that sodium chlorate oxidises fructose much more rapidly than glucose at pH 4. Chlorine dioxide, a reaction product, is estimated spectrophotometrically or colorimetrically. The difference between ClO_2 production by the solution under investigation and a standard fructose sample is ascertained. The method is applicable to fructose with from 0.05 to 0.5 per cent. of glucose.—H. G. Bray.

1575

RELAJZE, C. B. **Determinación cuantitativa de glucosa por micrométodo colorimétrico. [Quantitative estimation of glucose by a colorimetric micro-method.]** *Crón. Méd.*, Lima, 1951, **68**, 101-112. [Cát. Farm., Fac. Farm., Lima.]

A photocolorimetric method is described for the estimation of glucose in 0.05 ml. blood, which follows the technique of Haslewood and Strookman (Abst. 1252, Vol. 9) in the use of Na tungstate and CuSO_4 . CuSO_4 was contained in physiological saline and glucose standards were made up in isotonic CuSO_4 . Pollis and Sortwell (Abst. 3792, Vol. 16) used perchloric acid as precipitating agent,

but this is not favoured, nor is the use of BaSO_4 (Absts. 849, Vol. 14; 2897, Vol. 15).

The alkaline CuSO_4 reagent of Somogyi (Abst. 2896, Vol. 15) was used with the deproteinised blood filtrate and the best development of colour was effected by the addition of a simple sulphuric acid solution of any phosphomolybdic acid.

A. Hepburn.

1576

LEE, J. **A quick and simple method for blood-sugar estimation.** *Brit. Med. J.*, 1954, **ii**, 1087-1088. [Dept. Physiol., Med. Sch., Charing Cross Hosp., London.]

A method with dinitrosalicylic acid.

H. G. Bray.

1577

WOOD, E. C. **The determination of sucrose in sweetened condensed milk: a simplification.** *Analyst*, 1954, **79**, 780-781. [Clarence House, Clarence Rd., Norwich.]

Details of the calculation of sucrose content from polarimetric measurements are given.

H. G. Bray.

1578

HARWOOD, V. D. **Analytical studies on the carbohydrates of grasses and clovers. 7. The isolation of D-mannitol from perennial rye-grass (*Lolium perenne*).** *J. Sci. Food Agric.*, 1954, **5**, 453-455. [Dept. Chem., Univ. Edinburgh.]

For previous parts see Absts. 39, 240, Vol. 25. Hot-water extraction of perennial ryegrass removes D-mannitol along with contaminating carbohydrate material. The D-mannitol may be isolated by chromatographic separation on a charcoal column.—D. M. Walker.

1579

NORTHCOTE, D. H. **Electrophoresis of some neutral polysaccharides.** *Biochem. J.*, 1954, **58**, 353-358. [Dept. Biochem., Univ. Cambridge.]

The process takes place in borate buffer, pH 9.2, polysaccharides migrating to the anode. The use of the buffer is necessary even with polysaccharides containing *trans*-vicinal hydroxyl groups.

H. G. Bray.

1580

CARTER, G. H. and NEUBERT, A. M. **Rapid determination of starch in apples.** *J. Agric. Food Chem.*, 1954, **2**, 1070-1072. [U.S. Fruit and Veg. Prod. Lab., Prosser, Wash.]

1581

MOULD, D. L. and SYNGE, R. L. M. **Separations of polysaccharides related to starch by electrokinetic ultrafiltration in collodion membranes.** *Biochem. J.*, 1954, **58**, 571-585. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]

The chromatographic separation of polysaccharides related to starch and materials derived from them by chemical or enzymic treatment was achieved by electroendosmosis with strips of collodion membrane. Separation was by adsorption on the inner membrane surfaces. The collodion strips were stained with iodine and KI, and R_F values were measured. Comparison with reference dextrans of known average degree of polymerisation (DP) enabled the range of DP in different preparations to be estimated.—A. Hepburn.

1582

MOULD, D. L. and SYNGE, R. L. M. The electrophoretic mobility and fractionation of complexes of hydrolysis products of amylose with iodine and potassium iodide. *Biochem. J.*, 1954, **58**, 585-593. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]

The electrophoresis in agar jelly of partial hydrolysates of amylose in the presence of iodine and iodide permitted separation into different coloured zones. By a continuous fractionation process 4 dextrin fractions stained blue, red, orange and scarcely at all were isolated and purified. The degrees of polymerisation in the respective fractions, calculated as in the preceding Abst., were 40 to 130, 25 to 40, 19 to 25 and < 10.

A. Hepburn.

1583

HOLT, R. Volumetric determination of pectin as calcium pectate. *Analyst*, 1954, **79**, 623-627. [Fruit and Veg. Canning and Quick Freezing Res. Assoc., Chipping Campden, Glos.]

1584

GAILLARD, B. D. E. Chromatografisch onderzoek naar de samenstelling van de polysacchariden uit de celwand in verband met de analyse van ruwvoeders. [Chromatographic study of the composition of the polysaccharides of the cell wall, with reference to the analysis of coarse fodders.] *Thesis, Utrecht*, 1954, pp. 65. English summary.

Crude fibre, as 70 per cent. of the dry matter of pasture and straw, with pasture covering more than half of the agricultural surface of Holland, and fodder crops on much of the arable surface, is a most important product and economically demands closer investigation. There are no satisfactory methods for the separation and estimation of the several components of crude fibre. These are: pectins, i.e., polygalacturonic acids, soluble in 0.5 per cent. ammonium oxalate, with araban and galactan, polymers of arabinose and galactose. There may also be xylan and low-molecular polymers of glucose. The hemicelluloses are a complex mixture of which xylan is the main component

either in pure form or with glucuronic acid or arabinose and glucuronic acid. Araban and galactan occur regularly, and low-molecular forms of cellulose, β - and γ -cellulose, are also present in solution in the alkali used to extract the hemicelluloses. They are sometimes grouped as soluble in 5 or in 24 per cent. KOH. Nomenclatures differ. Cross Bevan cellulose is a mixture of cellulose and hemicellulose; what remains when pectins and lignin have been removed is "holocellulose".

The cell-wall components to be estimated are polysaccharides, and mono- and oligosaccharides not of that complex are removed by extraction with alcohol and benzene, which remove also pigments and fat. Pectins are removed with 0.5 per cent. ammonium oxalate. Not all the hemicelluloses can be extracted until lignin has been removed, but some lignin is soluble, with hemicellulose, in alkali and some hemicellulose in the reagents used to remove lignin. Attempts to estimate the loss of hemicellulose in removing lignin by estimation of loss of furfural-producing components err in principle because hexoses are present as well as pentoses and uronic acids yield furfural.

After a review of methods of estimating hemicellulose, 4 are discussed in detail, those of Weihe and Phillips (Abst. 987, Vol. 12) and of Wise, Murphy and d'Addico (*Paper Trade J.*, 1946, **122**, 11) and 2 now proposed. And finally the procedure for use with plant materials is set out in detail, a complete and a shortened method.

The complete procedure is as follows. Two samples of the ground hay or straw are extracted, one with 90 per cent. alcohol, the other with alcohol and benzene. In the first extract glucose, fructose and sucrose are estimated by chromatography; the residue is extracted with boiling water and fructosan is estimated. From the second sample the residue is extracted with 0.5 per cent. ammonium sulphate to remove pectins and the residue is treated with chloramine and ethanolamine to remove lignin. The holocellulose is extracted with 5 per cent. KOH, the soluble hemicellulose is hydrolysed with $N H_2SO_4$ and xylose, arabinose, glucose and galactose are estimated, again by chromatography. The residue is extracted with 24 per cent. KOH, and both soluble hemicellulose and the residue are hydrolysed with $N H_2SO_4$. The resulting sugars are estimated. The insoluble residue is pure cellulose.

In the shortened method the holocellulose is hydrolysed partly with $N H_2SO_4$ to give sugars and a complex residue and partly with 0.1 $N H_2SO_4$ to give sugars and Cross Bevan cellulose.—I. Leitch.

Crude fibre, as 70 per cent. of the dry matter of pasture and straw, with pasture covering more than half of the agricultural surface of Holland, and fodder crops on much of the arable surface, is a most important product and economically demands closer investigation. There are no satisfactory methods for the separation and estimation of the several components of crude fibre. These are: pectins, i.e., polygalacturonic acids, soluble in 0.5 per cent. ammonium oxalate, with araban and galactan, polymers of arabinose and galactose. There may also be xylan and low-molecular polymers of glucose. The hemicelluloses are a complex mixture of which xylan is the main component

either in pure form or with glucuronic acid or arabinose and glucuronic acid. Araban and galactan occur regularly, and low-molecular forms of cellulose, β - and γ -cellulose, are also present in solution in the alkali used to extract the hemicelluloses. They are sometimes grouped as soluble in 5 or in 24 per cent. KOH. Nomenclatures differ. Cross Bevan cellulose is a mixture of cellulose and hemicellulose; what remains when pectins and lignin have been removed is "holocellulose".

The cell-wall components to be estimated are polysaccharides, and mono- and oligosaccharides not of that complex are removed by extraction with alcohol and benzene, which remove also pigments and fat. Pectins are removed with 0.5 per cent. ammonium oxalate. Not all the hemicelluloses can be extracted until lignin has been removed, but some lignin is soluble, with hemicellulose, in alkali and some hemicellulose in the reagents used to remove lignin. Attempts to estimate the loss of hemicellulose in removing lignin by estimation of loss of furfural-producing components err in principle because hexoses are present as well as pentoses and uronic acids yield furfural.

After a review of methods of estimating hemicellulose, 4 are discussed in detail, those of Weihe and Phillips (Abst. 987, Vol. 12) and of Wise, Murphy and d'Addieco (*Paper Trade J.*, 1946, 122, 11) and 2 now proposed. And finally the procedure for use with plant materials is set out in detail, a complete and a shortened method.

The complete procedure is as follows. Two samples of the ground hay or straw are extracted, one with 90 per cent. alcohol, the other with alcohol and benzene. In the first extract glucose, fructose and sucrose are estimated by chromatography; the residue is extracted with boiling water and fructosan is estimated. From the second sample the residue is extracted with 0.5 per cent. ammonium sulphate to remove pectins and the residue is treated with chloramine and ethanolamine to remove lignin. The holocellulose is extracted with 5 per cent. KOH, the soluble hemicellulose is hydrolysed with $N H_2SO_4$ and xylose, arabinose, glucose and galactose are estimated, again by chromatography. The electrophoresis of whole serum has several defects: in particular, the abnormality in the β -region which averages out the distribution in a horizontal plane, and the non-planarity of boundaries. These can be abolished if the low-density group of lipoproteins (β) is removed by ultracentrifuging in NaCl solution. The removal of all the lipoproteins by centrifuging with NaNO_3 plus added D_2O prevents non-planarity in the α -region. A. Hepburn.

For part I see Abst. 1376, Vol. 23.

Several proteins when treated with H_2SO_4 for 36 hr. at $100^\circ C$. were hydrolysed, releasing from 34 to 37 per cent. of the amino-N produced by 5 N HCl under reflux, but without loss of tryptophan. In the presence of $N H_2SO_4$ or HCl, hydrolysis by H_2SO_4 was more complete, from 60 to 70 per cent., and loss of tryptophan was still very slight. The effects of different concentrations, temperatures and times were studied.

Preliminary rat feeding tests showed that an H_2SO_4 - H_2SO_4 hydrolysate of casein, after removal of the acids, would support growth, though not as well as either the original casein or a commercial enzymic casein digest.—C. Warner.

tion of the non-protein nitrogen of grassland
herbage. *J. Sci. Food Agric.*, 1954, 5, 515-
524. [Imperial Chemical Industries, Ltd.,
Jealott's Hill Res. Stat., Bracknell, Berks.]

The N.P.N. of samples of spring and autumn grass, white clover and alfalfa was analysed for amino-N after hydrolysis, ammonia N, amide N, nitrate N, choline N, betaine N and purine N,

amounting in all to from 77 to 88 per cent. of the N.P.N. The samples of herbage were extracted with boiling water and peptides and polysaccharides were precipitated with 75 per cent. alcohol. The filtrate was passed on to an ion exchange column after the removal of purines as their silver salts. After treatment with H_2S the purines were separated chromatographically, eluted from the paper and measured by ultraviolet absorption. Peptides were the main constituent of the N.P.N., which represented 23 to 30 per cent. of the total N in the sample.—D. M. Walker.

1619

OWEN, J. A., IGGO, B., SCANDRETT, F. J. and STEWART, C. P. The determination of creatinine in plasma or serum, and in urine; a critical examination. *Biochem. J.*, 1954, 58, 58, 426-437. [Dept. Clin. Chem., Univ. Edinburgh.]

The effect of different conditions on the estimation of creatinine by the Jaffé reaction was studied, including the effect of pH and the use of Lloyd's reagent and NC bacteria (*Corynebacterium urea-faciens*). The use of Lloyd's reagent with dilute urine or in conjunction with procedures which yield serum or plasma filtrates of pH less than 2.5 was found to be most satisfactory.—H. G. Bray.

ŠEPAČEK, M. Simultaneous determination of kynu-
renine and p-phenetidine in human urine.
Canad. J. Biochem. Physiol., 1954, 32, 604-
609. [Dept. Health and Welfare, Charlotte-
town, Prince Edward Island.]

The urine is hydrolysed with NaOH, which converts kynurenine to o-aminoacetophenone and p-phenetidine conjugates into the free base. These are distilled off, extracted from the distillate by ether and estimated spectrophotometrically. It is stated that p-phenetidine is not infrequently found in human urine.—H. G. Bray.

Lipoid Constituents

- 1623
HARTMAN, L. Determination of fat peroxides in the presence of phospholipids. *J. Sci. Food Agric.*, 1954, **5**, 476-481. [Fats Res. Lab., D.S.I.R., Wellington, N.Z.]
- Peroxides are reduced with FeCl_2 in benzene-methanol solution and the ferric iron is estimated by the addition of pyrophosphoric acid and 2:6-dichlorophenolindophenol. A comparison of results obtained by this method and the ferric thiocyanate method of Hills and Thiel (Abst. 1363, Vol. 16) was made with ox and mutton fats, dried buttermilk and several meat and fish tissues. The interference of phospholipins was considerable in the thiocyanate method; the present method was found to be free from such interference.
G. A. Garton.

STEWART, R. D. A method for the estimation of glycerides in blood. *Canad. J. Biochem. Physiol.*, 1954, **32**, 679-683. [Dept. Biochem., Dalhousie Univ., Halifax, N.S.]
- The lipids are extracted from 0.1 ml. whole blood with ethanol-ether. The solution is filtered, the solvents are removed and the lipids are saponified with KOH. The liberated glycerol is then oxidised with periodic acid to yield formaldehyde, which is distilled into Na sulphite solution. Addition of a solution of chromotropic acid in dilute H_2SO_4 produces a violet colour, the density of which is measured in a spectrophotometer. A standard curve is prepared from tripalmitin; allowance is made for glycerol derived from phospholipins by a separate estimation of lipoid P on the assumption that it is derived from lecithin.

WIERZCHOWSKI, Z. O nowych metodach oznaczania alkaloidów w łubinach pastewnych. 2. Mikrometody kolorymetryczne i wagowe. [New methods for the estimation of alkaloid content in fodder lupins. 2. Gravimetric and colorimetric micromethods.] *Roczn. Nauk rol.* [B], 1954, 67, 389-409. [Inst. Zootech., Dział Zwywnia Zwierząt, Oddział Paszoznawstwa.] Russian and English summaries.
- For part 1 see Abst. 121, Vol. 25.
- Both methods are based on the precipitation of the alkaloids from aqueous solutions as reineckates. In the colorimetric method the purple colour of these salts in acetone solution is used; in the gravimetric method the reineckate is dried and weighed and a factor, appropriate to the colour of the lupin and to the amount of alkaloid being measured, is applied. (From English summary.)—D. Harvey.
- 1638
BIGGERS, J. D. and CURNOW, D. H. Oestrogenic activity of subterranean clover. 1. The oestrogenic activity of genistein. 2. The isolation of genistein from subterranean clover and methods of quantitative estimation. *Biochem. J.*, 1954, 58, 278-282; 283-287. [Dept. Vet. Physiol., Univ. Sydney.]
1. The oestrogenic activity of genistein (5 : 7 : 4'-trihydroxyisoflavone) prepared synthetically or from clover (see part 2) was estimated with ovariectomised mice by the Allen Doisy vaginal cornification test. Subcutaneous injection of solutions of genistein in propylene glycol and groundnut oil showed potencies relative to oestradiol-3 : 17 β of 1.25 \times 10⁻⁵ and 4.53 \times 10⁻⁵.
2. In a series of steps involving ethanol extraction, the removal of chlorophyll and fats by benzene, ether extraction and chromatography of the resulting phenols on silica gel, a crystalline sample of genistein with a melting-point similar to that of the synthetic substance was obtained from fresh subterranean clover. The yield was equivalent to 369 mg. genistein per 100 g. dry matter.
- A reasonably accurate macro-method for the estimation of genistein in clover was evolved by calculation from the absorption spectrum of the crude phenolic mixture. A rough micro-estimation of genistein by visual comparison of the spots after paper chromatography was possible.
- The 4 varieties of subterranean clover studied contained large amounts of genistein, but other clovers contained none. Genistein, though a relatively feeble oestrogen, is possibly responsible for infertility in sheep grazing on subterranean clover.
- A. Hepburn.
- 1639
CHENG, E., YODER, L., STORY, C. D. and BURROUGHS, W. Estrogenic activity of some isoflavone derivatives. *Science*, 1954, 120, 575-576. [Iowa Agric. Exp. Stat., Ames.]
- The oestrogenic activity of 4 synthetic isoflavone derivatives, genistein (5 : 7 : 4'-trihydroxy-), daidzein (5 : 4'-dihydroxy-), biochanin A (5 : 7-dihydroxy : 4'-methoxy-) and formononetin (5-hydroxy : 4'-methoxy-) was estimated by uterine response in mice. Daidzein appeared to be the most active, genistein and biochanin A of approximately equal activity next and formononetin with only one free hydroxyl group was the least active.
- Biochanin A has been isolated from red clover, genistein from subterranean clover and the glucoside of daidzein from soya bean oilmeal. Oestrogenic activity in livestock feeds is probably due to isoflavone compounds and may be beneficial by stimulating weight gain (Title 5434, Vol. 24) or adverse when present in excess as in subterranean clover.—A. Hepburn.

COPPENET, M., DUCET, G., CALVEZ, J. and BATS, J. Microdosage colorimétrique du cuivre dans les végétaux par la 2-2' diquinoléine. [Colorimetric micro-estimation of copper in plants by 2:2'-diquinoline.] *Ann. agronom.*, 1954, **5**, 597-600.

The formation of a pink complex between Cu⁺ and 2:2'-diquinoline in organic solvents is the basis of this method. Hydroxylamine hydrochloride was used to reduce Cu²⁺ to Cu⁺.

A dried sample of plant material was treated with a mixture of perchloric and nitric acids and the resulting solution was neutralised with KOH. Sodium tartrate, hydroxylamine hydrochloride and isoamyl alcohol containing 2:2'-diquinoline were added, the mixture was thoroughly shaken, and after centrifuging the alcohol layer was removed and Cu was estimated colorimetrically. Fe, Mn and Zn in concentrations 10 to 20 times that of Cu did not interfere with the estimation.

A. Hepburn.

1646

GOMES, C. L., COUTINHO, A. R. and GOMES, M. L. L. Fluor em manteiga. Um problema sanitário. [Fluorine in butter: a health problem.] *Mem. Inst. Ezequiel Dias*, 1954, **5**, 41-54. [Belo Horizonte, Minas Gerais, Brazil.] English summary.

The possible dangers of NaF added as a preservative to butter are discussed. A qualitative test based on the method of Villavecchia ("Química Analítica Aplicada", 3. ed. castelhana, 1949) did not detect quantities lower than 10 mg. NaF per 100 g. butter. By a modification of the A.O.A.C. method of estimating fluoride estimation of 0.1 mg. was possible, and this method was found suitable for routine examination of butter samples.

GERRITSMA, K. W. and FREDERIKS, J. C. De bepaling van fluor in anorganische fosfaten. [The estimation of fluorine in inorganic phosphates.] *Chem. Weekblad*, 1954, **50**, 356-358. [Centraal Inst. Voedingsonderzoek T.N.O., Utrecht.]

Phosphates are so much used in the food and feedingstuffs industry that it is important to be able to estimate F reliably. The F is distilled off as silicofluoric acid and estimated colorimetrically with a zirconium alizarin lake, the preparation of which is described. HCl interferes but is eliminated by careful neutralisation with NaOH, with phenolphthalein as indicator. The distillation flask must be cleaned regularly with strong warm alkali because a deposit of amorphous silica interferes with the distillation.—I. Leitch.

1648

ARMSTRONG, W. D. and SINGER, L. Determination of fluoride by diffusion of hydrogen fluoride. *J. Dent. Res.*, 1954, **33**, 646. *Proc.* [Dept. Physiol. Chem., Univ. Minnesota, Minneapolis.]

KLEIN, E. Eine einfache Methode zur Bestimmung des anorganischen Blutjodes. [Simple

method of estimating inorganic iodine in blood.]

Biochem. Ztschr., 1954, **326**, 9-13. [Krankenhaus Stuttgart, Bad Cannstatt.]

The method depends on catalysis by iodide of the decolourisation of ceric sulphate by arsenious acid. After precipitation of proteins with trichloroacetic acid the serum is treated with an arsenious acid reagent at 37° C. and then with ceric sulphate, and the colour remaining is measured photometrically.

H. G. Bray.

1650

ZIEVE, L., DAHLE, M. and SCHULTZ, A. L. **Comparison of incineration and chloric acid methods for determination of chemical protein-bound iodine.** *J. Lab. Clin. Med.*, 1954, **44**, 374-377. [Dept. Med., Veterans Admin. Hosp., Minneapolis, Minn.]

A chloric acid method of digesting serum was compared with the incineration method of Barker *et al.* (Abst. 100, Vol. 21) in the estimation of protein-bound iodine. Serum samples were obtained from 14 myxoedematous, 22 hyperthyroid and 50 euthyroid patients and the protein-bound I of individual samples was estimated by both methods. Frequency distributions of the values obtained by each of the methods were compared. There was no significant difference between the methods in the hypo- or hyperthyroid group but the distribution in the euthyroid group was shifted upwards by from 1 to 1.5 µg. per cent. with the chloric acid method. Since the hyperthyroid values obtained by the chloric acid method were not shifted upward in a corresponding way, any advantage in time and simplification gained by the chloric acid method was offset by loss of discrimination between the higher euthyroid values and the lower hyperthyroid values. There was an overlap between the 8 and 11 µg. per cent. levels.

VANATTA, J. C. and COX, C. C. **Quantitative determination of serum sodium involving separation of cations on a resin column.** *J. Biol. Chem.*, 1954, **210**, 719-732. [Dept. Physiol., Southwestern Med. Sch. Univ. Texas, Dallas.]

One ml. of serum was applied to a cation exchange resin column in the Ba form and eluted with 0.05 M BaCl₂. The first 40 ml. containing the serum proteins was discarded. The next fraction

N.A. and R., April 1955

of 82.5 ml. was heated to 100° C., the Ba was precipitated as BaSO₄ over a 60 ± 1 sec. interval and removed by centrifuging, and an aliquot of the supernatant was run through an anion exchange resin column in the hydroxide form; the NaCl was converted to NaOH and estimated by titration. When corrections were made for the adsorption of Na on the BaSO₄ precipitate and a blank for the anion exchange column, good reproducible results were obtained, which differed within 1 per cent. when compared with the method of Butler and Tuthill (Title, p. 404, Vol. 1).—A. Hepburn.

WARREN, F. S. and DIMMOCK, F. A comparison of moisture determination methods for grain corn. *Canad. J. Agric. Sci.*, 1954, 34, 435-443. [Forage Crops Div., Central Exp. Farm, Ottawa.]

The moisture content of 122 samples of hybrid maize, ranging from 21.6 to 44.2 per cent., was estimated over a period of 4 years by the Brown Duvel oil distillation tester, electrical tester and ear shrinkage methods. The standard error for the electrical tester and ear shrinkage methods in comparison with the Brown Duvel method, an official and accurate method but unsuitable for large numbers of samples, ranged from 0.83 to 2.52 and from 1.67 to 3.17 percentage units of moisture. The electrical tester method was rapid and sufficiently accurate for general experimental work. The ear shrinkage method, although quite convenient, was less reliable.—A. Hepburn.

1667

LINCOLN, H. W., DIRKS, B. M. and HARREL, C. G. A method for the rapid determination of moisture in doughs and breads. *Cereal Chem.*, 1954, 31, 506-513. [Res. and Development Labs., Pillsbury Mills, Inc., Minneapolis, Minn.]

A sample of dough or bread is pressed between 2 tared filter papers, then rapidly dried between 2 infrared lamps while suspended from one arm of a projection reading balance. The procedure takes 10 min. or less. The data for moisture content agreed well with methods using a regular air oven or vacuum oven. The standard error of a single estimation was for doughs 0.45 and for bread 0.09 per cent. moisture.—A. Hepburn.
